This concept of public archaeology led to a concern among archaeologists for how they and their research interacted and interfaced with the public. Archaeologists took more interest in how their research was being used at public heritage sites and museums and in developing more ways to disseminate their research to the general public (Smith 2006). They designed publications and programs specifically for public consumption, and they invited the public to see and even participate in the process of archaeology. Some archaeologists worked with local schools to develop school-based archaeology programs and educational materials featuring archaeological research and processes (Little 2002). These type of public interactions with archaeology helped expand and redefine public archaeology into a much more diverse and dynamic concept. It was this attention to the public that connects archaeology with the present and helped open up applied archaeology to the multitude of domains that anthropologists have typically explored (Shackel and Chambers 2004).

Recent Applications of Archaeology

By the 2000s, archaeologists became more actively engaged in and had goals aimed at contemporary communities not just past ones. This concern for contemporary communities has thrust archaeologists into some unfamiliar territory as they have had to extend their work into the world of living people, which requires a different set of skills than archaeologists traditionally use. They had to learn how to collaborate with contemporary communities beyond interactions with stakeholders within the CRM context. They had to learn how to engage people and better understand the needs and desires of contemporary communities so that they could better develop projects to address them (Derry and Malloy 2003; Shackel and Chambers 2004; Stottman 2010). These goals were much more in line with what applied anthropologists had been doing, and archaeologists began to look to applied anthropology for the skills and methods necessary to work with contemporary communities. Along with this concern for contemporary communities and affinity with applied anthropology, the term applied archaeology was being used more frequently and outside of the CRM context. Applied archaeology was being used to refer to archaeology that resembled more applied anthropology than CRM (Brighton 2011; Derry and Malloy 2003; Downum and Price 1999; Stottman 2010).

The ways in which archaeology has been applied recently include a variety of domains most of which are focused on contemporary communities and their problems and issues.

Archaeology is used as a form of civic engagement, political action, social justice, activism, environmental justice, tourism, and collaboration with communities and has been used to address issues of climate change, genocide, agriculture, gender equality, racism, homelessness, poverty, hunger, and disasters just to name a few (Little and Zimmerman 2010). Many of these more recent applications of archaeology have come from academic-based researchers and programs challenging the academic and applied dichotomy that developed as a result of CRM. Based on these recent applications of archaeology, it is clear that at this point in time, archaeology has seen more applications than ever before. These applications push the notion of archaeology from just being useful to the public to being instrumental in many issues that contemporary communities face.

Key Issues/Current Debates

What Is Applied Archaeology?

Although I have posed a working, if not simple, definition of applied archaeology and constructed a somewhat limited history of its development, the key issue for applied archaeology and what has been debated for some time is determining what it is. Despite the fact that archaeology has been and is applied in many different ways, the term applied archaeology is problematic for many archaeologists. Although I have clearly shown that many archaeologists currently that the applied archaeological work that they do is closely aligned with applied anthropology in goals and practice, some archaeologists do not have the same affinity with applied anthropology. Also born out of critical and Marxist perspectives, praxis has been seen as a way to provide the methodological basis for connecting their research with contemporary communities by becoming politically engaged in their causes. This perspective has been most exemplified by Randall McGuire (2008) and others who have become politically engaged with communities in an activist way. Although applied anthropology has greatly influenced recent applications of archaeology, there are other ways that archaeologists have applied their work with similar goals. It also suggests that perhaps applied archaeology is an inadequate and problematic term to encompass all applied work. Thus, there has been debate about what to call these more recent applications of archaeology.

Clearly some saw the use of the term applied archaeology as an obvious description for what it is that they do and that it is related to applied anthropology. Archaeologists who have sought to expand the applications of archaeology have struggled with the semantics of this type of archaeology. Because applied archaeology is most commonly associated with CRM, many archaeologists felt that it did not adequately describe what they do. Some sought simply to redefine applied archaeology to include archaeologist's focus on contemporary communities and lessen CRM's dominance of the term, while others felt that more specific labels were necessary to adequately describe their work (Brighton 2011; Stottman 2010).

In order to distinguish more recent applications of archaeology from the traditional concept of CRM applied archaeology, a variety of labels have been used to describe them, such as action archaeology, activist archaeology, community archaeology, and collaborative archaeology just to name a few. It has been argued that such archaeologies amount to "an activist niche in archaeology" and that what is needed is a label that can focus on what archaeologists are trying to do with this work rather than just a niche (Atalay et al. 2014: 8). It has been suggested that what archaeologists want to do with activist-type work is more than an application of archaeology they want it to be transformative not just for communities but also for archaeology itself (Atalay et al. 2014).

The definition of applied archaeology that I posed in this entry is an attempt to redefine the term so as to more broadly encompass applied work, using the model of applied anthropology (Kedia and van Willigen 2005; Shackel and

Chambers 2004). Although this definition generally describes the breadth of applied work that is being done, it does not however capture the essence of activism and transformation that some seek. The debate over terms and labels may seem like a superficial semantic discussion, but it is important for charting the future of applied work. Will applied archaeology be formalized like applied anthropology? Will applied work be splintered into individual niches? Or will it be transformative? These are questions that will be debated as applied work in archaeology moves forward.

The Relevancy of Archaeology

Underlying much of the applied archaeological work conducted around the world is the relevancy of archaeology. Is archaeology useful and relevant and to whom? These are questions that archaeologists debate and applied archaeology is central to this debate (Gunn 1978). The relevancy of archaeology was largely unquestioned in the context of CRM with the full weight of government mandates behind it; however as archaeologists increased their interactions with the public and were compelled to justify their work to the public, they began to question archaeology's relevancy beyond CRM. Archaeologists began to reflect on the relevancy of their field and document the contributions that archaeology has made to societies around the world (Little 2002; Sabloff 2008). Most of these contributions were conducted within applied contexts, and it is clear that more recent applications of archaeology that focus on addressing the issues and needs of communities expand archaeology's relevancy to the public (Rockman and Flatman 2012).

Archaeologists have recognized that not only do they need to better inform the world of archaeology's contributions to society, they also need to think about their research and their projects in ways that also prioritize the benefits that such work can and should have to the public. Whether archaeology is and how it can be useful to society has been the subject of discussion and debate, being a topic at conferences and forums for some time (Dawdy 2009). Similar discussions and debates have taken place regarding archaeologist's stature within public media. For example, a recent discussion forum examined the role of archaeologists as public intellectuals (Tarlow and Stutz 2016). An important aspect of that discussion was not just about applied archaeological work but also about how that work is applied to media and the way the public consumes information. Certainly the work that archaeologists do has something to contribute to solving society's problems and issues, but if archaeologists cannot serve the role as a public intellectual, being called on to provide a perspective on non-heritage issues such as climate change, then archaeology's relevancy is substantially diminished. This is but just one example of discussions involving relevancy. The issue of archaeological relevancy will always be discussed and debated among archaeologists, and applications of archaeology will be at the center of it.

The Challenges for Applied Archaeology

Some of the challenges for applied archaeology mirror those that plagued its colonial inception. One of the reasons that archaeologists became wary of using archaeology to affect communities was the unintended consequences that such applications could have for those communities (Dawdy 2009). As archaeologists have recently become more engaged with contemporary communities and applying archaeology to address societal problems and issues, a major risk with this type of work is unintended consequences. This type of work also places archaeologists in unfamiliar situations often without the skills needed to negotiate them. With new opportunities for the application of archaeology comes the need for developing the skills, methods, and ethics to work with contemporary people (Derry and Malloy 2003; Stottman 2010). It risks changing what archaeology is and what archaeologists do to accommodate the goals of benefiting contemporary communities with archaeology.

As archaeologists work with contemporary communities through their research and projects, there may be unintended consequences for those communities and archaeology. Working with these communities can create unequal power relationships and sometimes force archaeologists to take sides in political battles (McGuire 2008). Although the intent is to benefit communities with archaeology, it is possible that some can be harmed by good intentions (Atalay et al. 2014; Stottman 2010). It will be a challenge for archaeologists doing applied activist work to collaborate fully with communities in order minimize the possible negative consequences of their work.

Another major challenge for applied archaeology is to continue to find ways to make and keep archaeology relevant to the public at large and retain its identity. The push for relevancy and to find more uses and applications of archaeology threatens to lead the field away from its core identity focused on excavation, material culture, and heritage. Is it still archaeology if there is no excavation involved or research results are not focused on understanding the past? Can we conceive of an archaeology that applies only archaeological thinking or method to address contemporary societal problems and issues? Applied archaeology may well redefine what it means to be an archaeologist, and thus, as we move forward, we must constantly reflect back on who we are and what archaeology is.

International Perspectives

Like all archaeology, applied archaeology is contextual. Clearly my perspective is North American centric, which represents the context of the applied work that I do and with which I am most familiar. Regardless of this fact, I think that the history of and issues facing applied archaeology that I have discussed will be recognizable to those doing applied work around the world. Archaeologists doing applied work share in the discussion above but with the nuances of their own context. Some aspects of the discussion may be more accentuated, while others are less relevant. Below I will attempt to highlight some of the ways that archaeology is applied which are perhaps more global in perspective.

Most developed countries around the world have some form of government-regulated cultural heritage resources process that is similar to CRM. Much of my discussion about CRM as applied archaeology applies to similar processes in other countries, such as that it represents much of the applied archaeological work being done there. One area of difference is that nationalistic archaeology gets a great deal of attention internationally, where government-supported archaeology is applied toward building national identities or establishing links to disputed regions, which can sometimes harken back to archaeology's colonial legacy. However, such archaeology has also been applied to build cooperation in disputed regions such as the work that Israeli and Palestinian archaeologists have done (Little and Zimmerman 2010).

Applied archaeology has a much larger role in heritage studies internationally than in the United States. Archaeology has been employed to identify and interpret important heritage sites not only as part of nationalistic archaeology but also to serve the heritage tourism industry. For many countries around the world, heritage tourism is a major industry that is integral to economies. This industry has spurred academic and applied archaeological and anthropological research through heritage studies programs (Little and Zimmerman 2010; Smith 2006). Such research is used to help develop heritage sites and museums for tourism but also to study the effects of heritage tourism on local cultures and economies. Activist components to heritage research seek to collaborate with local communities through archaeology so that they also have a stake in the decisions being made about their archaeological resources and the positive and negative effects that heritage tourism can have for them (Atalay et al. 2014; Little and Zimmerman 2010).

Also of concern globally are issues such as hunger, climate change, and genocide, for which archaeology has been employed. Archaeologists have used their work in understanding the development of agriculture to help find solutions to hunger in parts of the world where modern agriculture is failing (Little and Zimmerman 2010). They have also used their studies of human and environmental interaction to better understand the effects that culture has had on the world's environments and how it can be applied to help understand climate change (Rockman and Flatman 2012). Furthermore, archaeologists have been employed to help investigate genocide to bring attention to such atrocities and build cases against groups that have perpetrated the crimes.

Future Directions

What does the current trajectory of applied archaeology mean for CRM? Although more recent applications of archaeology tend to be derived from academia, CRM is still applied archaeology and should not be left out of the current concern for contemporary communities and their problems and issues. I and others see great potential for CRM archaeology to be more cognizant of and applicable to address societal problems and issues (Atalay et al. 2014; McGhee and McDavid 2009). CRM has the ability to provide the field of archaeology the most consistent access to people and communities on a daily basis. Some parts of the CRM system have already begun to embrace a concern for how the process and products of CRM articulate with communities. There is more community collaboration within the CRM process, and community projects have been the focus of alternative mitigation strategies. For example, educational materials have been developed for local school children using the results of CRM projects and as a way to provide tangible returns to fill the needs of affected communities. The future of applied archaeology requires the removal of academic vs. CRM dichotomies and fostering activist approaches within CRM.

It is likely that applications of archaeology will continue to grow and develop as the use of archaeological knowledge is limitless, since society's problems and issues are immense. The benefits and uses of archaeology for contemporary communities are not restricted to traditional concepts of heritage and the past. Archaeologists are also extending the uses of the field beyond the traditional knowledge we gain to using the process of how we do archaeology. Archaeologists are seeking uses for archaeology in many aspects of society that may seemingly have very little relation to heritage. More recently, archaeological methods and techniques have been used to locate victims of 911 and the aforementioned work in climate change, agriculture, and justice for victims of genocide (Little and Zimmerman 2010). Public archaeologists have found that using the process of doing archaeology has far greater potential in education than the products of that process (Atalay et al. 2014). The future of applied archaeology is only limited by our concept of archaeology and for what it can be used. In order to expand the uses of archaeology, we have to first think about archaeology as not just about the past. It is about how the field articulates with the present and what we can learn, not just about people in the past but also about people in the present.

Given the current trajectory of applied work, the future of applied archaeology could mean the end of applied archaeology as a term or label. As more recent applications of archaeology have become mainstream within archaeology, there may be a point in the future where all archaeological work has some applied component or goal, making applied archaeology, as a term, irrelevant.

Apricot: Origins and Development

Alison Weisskopf and Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

Basic Species Information

Apricot, sometimes known as Armenian plum (derived from a mistaken belief of an Armenian origin), is the common name of *Prunus armeniaca* L./*Armeniaca vulgaris* L. The name apricot derives from the Arabic *al-birquq* through Byzantine Greek *berikokkia* from Latin *malum praecoquum* – early ripening fruit. The Latin *Prunus armeniacum* is a reference to an early believed origin in Armenia, which is one of the places where these trees are wild.

Apricot is a deciduous tree up to 10 m with broad ovate leaves, self-fertile white – rarely pink – flowers produced singly or in pairs before the leaves in spring. Some cultivars are self-compatible while are others are self-incompatible. Wild forms are fully interfertile with cultivated populations. Apricots are grown for their large

fleshy fruit, a drupe with glabrous or pubescent yellow to orange exocarp and a soft mesocarp. The endocarp is lignified and slightly grainy on the outer surface. There is a pronounced ridge along the ventral suture. The seeds or kernels produce laetrile (cyanide) in wild forms, and some cultivars are bitter to avoid predation (Zohary et al. 2012). In other cultivars, apricot kernels can be eaten in substitution for almonds, especially in China where they are commonly roasted to make them palatable (Simoons 1991). Apricot kernels are also used to flavor Amaretto liqueur and biscuits (van Wyk 2005).

Apricots are cultivated in temperate, subtropical and continental regions. They require cool weather for dormancy, and the trees can survive winter temperatures down to −30 °C, but the buds and flowers are not frost resistant. The fruit needs dry weather for maturation. Trees usually bear fruit the 4th or 5th year after planting.

Major Domestication Traits

Wild apricots have a disjunct distribution in the Caucasus region and in eastern Asia. These wild forms are characterized by smaller fruits and leaves and spiny branches (Lu and Bartholomew 2003; Gabrielian and Zohary 2004). In China, free-growing and possibly wild populations of a number of varieties are reported from hilly areas around much of northern and western China (Ningxia, Qinghai, Shaanxi, Shanxi, Nei Mongol, Liaoning, Jiangsu, Shandong, and Sichuan). *A. vulgaris* var. *vulgaris* is reported to occur in pure stands in the Illi prefecture of Xinjiang. While in China, these occur between 600 and 3000 m elevation; in Armenia, they are found at 1200–2100 m only. Modern genetic diversity is suggested to have three centers of diversity (Yilmaz and Gurcan 1977; Maghuly et al. 2005), including one focused on the Caucasus, one on northwestern South Asia, Central Asia, and Xinjiang, and one on China. This strongly suggests that wild populations in Xinjiang and Armenia have contributed to cultivar diversity, although the origins of early cultivars may only have taken place in China.

Timing and Tracking Domestication

Archaeobotanically, apricots may be recognized from endocarp remains that differ from related tax (e.g., Fig. 1). Based around the Caucasus center of wild apricots are a number of early finds. These include archaeological evidence from the Eneolithic at Garni and Shengavit in Armenia (Arakelyan 1968), Eneolithic sites in the Ukraine ca 4000–2800 cal BCE (Zohary et al. 2012), and sixth and fourth millennia cal BCE sites in the Carpathian-Dniester region (Monah 2007). It is unclear if this indicates a formerly more widespread wild distribution or early translocation of cultivated trees.

In the East, archaeobotanical evidence points to origins of cultivars in Central China. It is difficult at this stage to separate stone remains of wild versus domesticated apricots in early assemblages. The earliest finds probably represent gathering, such as from Kuahuqao (6000–5400 BCE) in the Lower Yangtze region, alongside many wild nuts and fruits, including the related *Armeniaca mume*. Later in the Longshan period (after 2500 BCE) and Bronze Age (second millennium

Apricot: Origins and Development, Fig. 1 Illustration of endocarps (stones) of apricot (*Armeniaca vulgaris*), *left*, compared to the Japanese apricot (*Armeniaca mume*), *right*

BCE), there are several sites with apricot from Central China (Hosoya et al. 2010). The early history of apricot in China is intertwined with the mume apricot, or Japanese apricot, *A. mume* Siebold (syn *Prunus mume*), which today goes by the Chinese name *mei* distinct from *xing* used for true apricot. However, it is thought that *mei* might have originally referred to true apricots. *A. mume* is an important cultivar, especially in South China, Japan, Korea, northern Laos, and Vietnam. It is native to the slopes below 3100 m in western Sichuan and western Yunnan (Lu and Bartholomew 2003). Disjunct wild populations are also reported from northern Taiwan. This species has sour fruits which are normally made edible through drying, salting, or pickling (Simoons 1991). True apricots may have been used in similar fashion, with sweet forms developing later (or even outside of China). The first finds of apricot beyond its Chinese wild distribution is in Neolithic Kashmir by or shortly after 2000 BCE (Lone et al. 1993). Much later finds include late First Millennium BCE in Nepal (Knorzer 2000) and in the Sampula Cemetery in Xinjiang (Jiang et al. 2009).

Apricots reached the Mediterranean region late, probably as introductions from Iran and Armenia around the third century BCE. Within a few hundred years apricots were well established in Spain, Turkey, Greece, and Italy (Zohary et al. 2012). They were taken to the Americas by the Spanish in the fifteenth century (Yilmaz and Gurcan 1977).

Arabian Peninsula: Islamic Archaeology

Andrew Petersen
School of Archaeology, History and Anthropology, University of Wales Trinity Saint David, Ceredigion, UK

Introduction

As the birthplace of Islam, the Arabian Peninsula holds a special place within the Muslim religion and culture. Despite this the archaeology of the region has not been investigated to the same extent as many other parts of the Middle East, and there are still major sites and themes which are yet to be explored. The reasons for this situation are largely historical, and currently our understanding of the archaeology of the region is being transformed through new international and national projects throughout most of the Peninsula.

Definition

The Arabian Peninsula is a huge area covering more than one million square miles with a considerable diversity of climate, topography, and culture. It is located between Africa and Asia and with its own tectonic plate may be considered a subcontinent although conventionally it is regarded as part of Asia. Seven countries are located entirely within the Peninsula (Saudi Arabia, Kuwait, Bahrain, Qatar, United Arab Emirates (UAE), Oman, and Yemen), while large parts of Jordan and Iraq may also be considered part of the region. Saudi Arabia is overwhelming the largest country in Arabia and shares a common border with all of the other states. The regional significance of Saudi Arabia is further reenforced by the fact that it contains the two holiest sites in Islam, the sacred cities of Mecca and Medina. Despite being home to ancient civilizations, the modern states of Arabia are mostly fairly recent, and with the notable exceptions of Oman and Yemen, all are less than 200 years old.

Historical Background

Prior to the development of European interest in Arabia, inhabitants of the region had shown some interest in the antiquities of their homeland. For example, as early as the seventh century, the authorities in Mecca had investigated the antiquity of the Ka‘ba and the earlier foundations buried beneath. Similarly the early tenth-century author Hasan ibn Ahmad al-Hamdani considered the antiquities of Southern Arabia in his book *Kitab al-Iklil* (Faris 1938). However, systematic investigation of ancient remains recognizable as modern archaeological practice was largely the result of European interests in the region. The archaeological investigation of Arabia began in different areas at different times although the earliest scientific exploration of the Peninsula was carried out by the Danish Expedition of 1761–1767 of which Carsten Niebhur was the only survivor. Although the expedition mostly retrieved information about the coast of Arabia with little information from the interior, it was unique because it was the first attempt to systematically document the region (Niebhur 1792). In the nineteenth century there were many expeditions to Arabia which included documentation of antiquities; the majority of these focused on northwest Arabia though Yemen was also an area of considerable interest. Although many of these early explorations collected information relevant to Islamic archaeology, most were concerned primarily with pre-Islamic remains and in particular the ancient Arabian civilizations. Interest in Islamic civilization was generally restricted to ethnographic studies although there was some interest in Islam as a religion with a fascination for the holy cities of Mecca and Medina. Early explorers who offered descriptions of antiquities include the Swiss explorer Burckhardt famous for rediscovering Petra in 1812. In addition Burckhardt made a trip to Mecca in 1814 where in the guise of a Muslim, he made a detailed study of the holy sites of Mecca including the Ka‘ba

(Burckhardt 1829). Nearly forty years later in 1853, Sir Richard Burton disguised himself as an Afghan Muslim and visited Mecca and Medina making detailed notes and measurements of all he saw within the holy cities (Burton 1893).

Against the background of increasing European interest in the antiquities and culture of Arabia, the political configuration of the Peninsula in the nineteenth century was gradually evolving. While the Hejaz (western region), Yemen, and al-Hasa were under Ottoman Turkish control, the interior Najd was the home to a growing fundamentalist Islam which was the seed of the modern Saudi state. In the Arabian/Persian Gulf on the east coast of Arabia, Oman and a number of tribal territories along the coast were brought under British influence in order to protect the security of the sea route to British India. Despite the British presence in the Gulf, there was little interest in the antiquities of the area although records made by British officials have subsequently become indispensable for the study of archaeology in the area. Following the collapse of the Ottoman Empire in 1918, there was political turmoil in the region, and little archaeological research was carried out until after World War II.

From the 1950s onward there was increasing interest in the archaeology of Arabia partly funded by the quest for oil in the region. Important work was carried out in Bahrain and the Eastern Province of Saudi Arabia (formerly al-Hasa province) revealing a complex early society with links to Mesopotamia and India. Although the focus of this archaeology was on the pre-Islamic period, the presence of Islamic-period remains often overlying those of earlier periods could not be ignored. In general however Islamic archaeology was not regarded as something of interest in its own right. This is reflected in the works of Creswell who was famously dismissive of the Arabian contribution to Islamic architecture (King 1993). Even within the highly religious Kingdom of Saudi Arabia, the interest in antiquities in general and Islamic antiquities in particular was muted, and on occasions there seemed to be a hostility to archaeological research. The suspicion of archaeology was partly a wariness that archaeological sites could become shrines and as such used as a focus for unorthodox worship. There was also a sensitivity to interpretations of archaeological material which might conflict with accepted historical narratives. Examples of studies which have challenged Muslim historiography include Patricia Crone's work which suggested that Mecca was not a major trading center (Crone 1987) and Nevo and Koren's assertion that Muhammad was not fundamental in the establishment of Islam in Arabia (Nevo and Koren 2003). Although both these studies have largely been disproved by archaeological and historical research, they are both sensitive issues for the Saudi religious authorities.

The granting of full independence to the Gulf States and growing urban and industrial infrastructure during the 1970s led to a growing interest in protecting and investigating the antiquities of Arabia. For example, the government of Qatar commissioned the *Qatar Archaeological Report* which was the first detailed archaeological survey of the country and is still an important source of information for the Islamic and pre-Islamic archaeology of the country (De Cardi 1978). Also during this period the Saudi government began a comprehensive survey of archaeological sites throughout the kingdom and initiated a major project recording the Darb Zubayda (Muslim pilgrimage route from Baghdad to Mecca). The 1970s also saw the first publication of the *Proceedings of the Seminar for Arabian Studies* under the initiative of John Dayton. The Seminar provided a forum for the discussion and publication of issues related to the archaeology and culture of Arabia which is still continuing today. This period also saw the first excavations at Qaryat al-Fau by King Saud University under the direction of Abd al-Rahman al-Ansary. This major pre-Islamic settlement in central Arabia (first century BCE and fourth century CE) is important for understanding the Islamic archaeology of Arabia because it indicates the indigenous roots of Arabian civilization (al-Ansary 1982). However, the most important project for Islamic archaeology was the excavation of the early Abbasid site of al-Rabadha by Saad al-Rashid in the late 1970s and early 1980s (al-Rashid 1986). Although the site had been inhabited prior to the eighth century, the construction of the pilgrimage route from Baghdad to

Mecca led to the development of the settlement as a major stopping place. The architecture and finds from the site indicate a sophisticated urban settlement with extensive trade connections.

Since 1980 the number of archaeological projects in Arabia has multiplied with both research projects and developer-funded excavations transforming our understanding of the archaeology of the region.

Key Issues

The archaeology of the Islamic period in Arabia is a subject which is developing very quickly, and it is likely that many of the current questions and theories will be modified or replaced as new data becomes available. For the present a number of areas of research dominate our understanding of this period which relate to urbanism, maritime/coastal archaeology, water management and agriculture, and trade and pilgrimage routes.

Urbanism

The birth of Islam in Arabia is intimately associated with urban life in Mecca and Medina, while the spread of Islam outside Arabia is also associated with cities and towns. Before the 1980s archaeologists working further north in Syria, Palestine, and Jordan tended to ignore this Arabian urban heritage looking instead at Islamic cities simply as developments of earlier Roman and Byzantine urban settlements. The discovery of both pre-Islamic and early Islamic cities within Arabia has led to a reassessment of this cultural bias. New research based on excavations at sites such as ‘Aqaba in Jordan has suggested that the pattern for Islamic settlement may in fact originate in Arabian forms of urban development (Fig. 1; Whitcomb 1996). In addition to an interest in the contribution of Arabia to early Islamic urbanism, there is also a growing interest in towns of the late Islamic period (Petersen 2009). In part this is connected with an interest in the origins of the modern Gulf cities such as Dubai, Abu Dhabi, Ras al-Khaimah, Doha, and Muscat (Peterson 2007). There is also a growing interest in traditional urban architecture which is seen as environmentally and socially more suitable than modern energy-intensive structures.

Maritime/Coastal Archaeology

Although typical images of Arabia are largely dominated by arid mountains and sand deserts, it also has coasts on three seas (the Red Sea, the Indian Ocean, and the Persian/Arabian Gulf). The majority of settlement in Arabia is located near the coast with traditional occupations including fishing, pearl diving, and maritime trade. A number of port cities have been excavated (e.g., ‘Aqaba,

Arabian Peninsula: Islamic Archaeology, Fig. 1 The Mamluk and Ottoman fortress at ‘Aqaba, Jordan, excavated between 2000 and 2003. Originally founded in the thirteenth or fourteenth century, the majority of the standing building dates to the 1500s and later. The site of early Islamic ‘Aqaba excavated by Donald Whitcomb in the 1980s is approximately one kilometer to the west

Qalhat, Bahrain, Ras al-Khaimah, Sohar, Jumeirah, Ras al-Hadd) with finds which indicate wide-ranging long-distance trade with sub-Saharan Africa (Kenya and Tanzania), the Far East (China, Vietnam, and Philippines), and India (Gujerat). Recently there has been considerable interest in the pearl industry in the Gulf with major excavations at Zubarah and Ruwayda in Qatar revealing much about the organization and material culture of a nineteenth-century pearling center (Petersen and Grey 2010; Richter et al. 2011). Fishing has also attracted attention with the mapping and excavation of fish traps demonstrating considerable continuity from the pre-Islamic period to the present day.

Water Management and Agriculture

One of the distinguishing features of the Arabian Peninsula is the scarcity of water, and over the centuries the inhabitants have developed sophisticated means of water catchment and retention. Some areas such as Yemen and southern Oman benefit from seasonal monsoon rains and have developed complex irrigation and agricultural systems which maximize the available water. In other areas such as Oman and the UAE, water is brought from the mountains into urban agricultural areas by means of underground water channels (*qanat*s). However, in most of Arabia water is derived from wells or springs and is extremely scarce. Nomadic Bedouin are generally dependant on wells both for their herds and for themselves, and complex arrangements have developed to enable the water to be shared between different tribes. One of the key issues in the study of water management is the origin and the development of the *qanat* system which investigators have traditionally attributed to pre-Islamic Persian occupation. While some *qanat*s certainly predate the advent of Islam, it also appears that many of the *qanat*s in Arabia were built during the Islamic period (Lightfoot 2000).

Trade and Pilgrimage Routes

While Arabia had extensive connections through maritime trade in the Indian Ocean and the Gulf, there were also caravan routes which connected the towns and cities of the coast with the interior and the more settled regions of further north. The most famous caravan route is undoubtedly the incense road which connected south Arabia with Syria via the caravan cities of Medain Saleh and Petra. Although the incense trade seems to have declined before the advent of Islam, the route continued to be of importance during the Islamic period as the Syrian *hajj* route. During the Ottoman period this route became particularly significant as the link between the Constantinople and Mecca increasing the legitimacy of the Sultan's title of Protector of the Two Shrines (al-Rashid 1979, 1980; Petersen 2012). The network of pilgrimage routes which cover Arabia not only provided access to the holy cities of Mecca and Medina but also stimulated trade and the local economies of the towns, villages, and nomadic territories through which they passed. Other important caravan routes linked the settlements on the Gulf coast with those of Oman via the Wadi Jizzi. The advent of Islam increased the traffic on all the existing routes as well as creating new roads such as the Darb Zubayda.

Current Debates

The large number of archaeological investigations in Arabia as well as the increasing interest in the history and culture of the area has raised a number of difficult methodological problems which need to be addressed. These may be summarized as (1) how to incorporate churches and Christianity into the Islamic archaeology of the region; (2) how to deal with the archaeology of Mecca and Medina in the face of rapid development; (3) how to investigate the archaeology of slavery within the region; and (4) how to deal with the archaeology of different religious sects.

Churches and Christianity

Both historical sources and archaeological excavations point to a significant Christian population in Arabia before the advent of Islam. In eastern Arabia excavations have revealed churches and monasteries at a number of sites including Failaka in Kuwait and Sir Bani Yas in

the emirate of Abu Dhabi. There is also significant anecdotal evidence of the discovery of churches in Saudi Arabia although these are generally unpublished (see, e.g., Langfeldt 1994). The general assumption is that all the churches are of pre-Islamic date and ceased to function soon after the time of Muhammad; however, it is probable that at least some of these communities continued well into the Islamic period. The challenges include recognizing the archaeological evidence of continued Christian presence into the Islamic period and incorporating this into "Islamic archaeology" (see also Insoll 2005: 198–9).

Archaeology in Mecca and Medina

Like many religious sites around the world, Mecca and Medina have both a spiritual and an archaeological significance. The spiritual dimension of the cities includes both practical considerations related to the accommodation of ever-increasing numbers of pilgrims and also philosophical questions related to the embodiment of the faith in structures and locations. The archaeological dimension relates to the fabric of buildings as well as stratigraphic deposits and features which may be found within the cities. Massive building works in recent times have meant the destruction of much archaeological material, and it has been estimated that up to 90% of the historic fabric of the cities has been destroyed. Reconciling the needs for accommodating vast and increasing numbers of pilgrims with the historic remains is undoubtedly a challenge and will involve some difficult decisions; however, archaeological documentation can still be carried out whatever the ultimate fate of particular historic structures.

The Archaeology of Slavery

The archaeology of slavery in the New World, in Africa, Europe, and elsewhere is an area of research which has seen growing interest in recent years. Within the Islamic world there have been a few attempts to investigate slavery through archaeology, but much more needs to be done. In Arabia there is considerable scope for investigating the phenomenon both because it survived much longer than elsewhere and also because there is potential for considerable material to have survived.

The Archaeology of Religious Sects

Although Muslims generally see themselves as part of a single community (*ummah*), there are many different sects and divisions, the most prominent of which is between Shia and Sunni Muslims. Within Arabia the majority of the current population is Sunni (specifically *Wahidun*, *Salafist*, or *Wahabbi*) although there are also significant numbers of Shia in the Eastern Province of Saudi Arabia, Bahrain, and Yemen. In addition Oman has a sizeable Ibadi population, and there are Sufi orders which although rare in present-day Arabia were a significant feature in Ottoman times. The recognition of these sects within archaeology is important to inform modern perceptions of heritage and to gain a full understanding of the past cultures.

International Perspectives

Archaeology in Arabia has always had international dimensions because of both the religious significance of the region and international strategic and economic interests in the area. For example, Russian archaeological expeditions were carried out in south Yemen during the period when the country was allied to the Soviet Union (1969–1992), while many of the early archaeological discoveries in Saudi Arabia were linked to the work of Americans working for the Aramco oil company. Other countries involved in Arabian archaeology include Denmark (with Danish teams carrying out excavations in Qatar, Bahrain, Kuwait, and the UAE), Japan, and Britain.

Future Directions

The rapid development of much of Arabia combined with a growing appreciation of the value of traditional heritage and culture means that archaeology is of growing importance for the region.

Islamic archaeology is particularly significant due to its connection with the modern population of the area and because it is so well represented in the material record. Aspects of archaeology likely to develop our understanding of the Islamic period in Arabia include aerial survey, environmental studies, and heritage development, as well as some theoretical approaches adopted from historical archaeology.

Aerial Survey

The large and often inhospitable interior of Arabia lends itself to aerial survey, which has been used in the region since the early twentieth century. Although security concerns and territorial disputes have restricted the use of aerial survey in archaeology, the development of new techniques has opened up new possibilities. These include the use of declassified and open-source satellite imagery which together with increased accessibility to historical imagery have enabled significant discoveries of archaeological sites (Kennedy and Bishop 2011). In addition the development of unmanned aerial vehicles (UAVs) has given archaeologists the opportunity to selectively survey areas both as a means of site prospection and in order to monitor known archaeological sites.

Environmental Studies

Although environmental studies have long been part of prehistoric archaeology in the Middle East, their application to historic-period sites is infrequent. However, as the number of sites investigated increases, it is likely that it will be possible to investigate long-term patterns of production and consumption throughout the Islamic period. Of particular interest is the range and quantity of agricultural produce used on different sites, with associated implications for cultural adaptation and climate change.

Heritage Development

The growing importance of archaeology and historic buildings in Arabia is reflected in the increased attention being given to the presentation of sites and monuments as well as the development of museums. The Islamic period is particularly well presented in museums, while a number of specifically Islamic sites have been added to the UNESCO World Heritage list; these include the al-Turaif district in Saudi Arabia, Zubarah in Qatar, Zabid and San‘a in Yemen, and Bahla Fort in Oman. In the future it is likely that the number of World Heritage sites in the region will increase, as will local engagement with archaeology and heritage (Figs. 2, 3, and 4).

Arabian Peninsula: Islamic Archaeology, Fig. 2 Corner tower of al-Jahili Fort in al-Ain, UAE. The fort dates mostly from the nineteenth to twentieth century and is one of nine forts in the al-Ain Buraimi Oasis. It was excavated in 2008 as part of a comprehensive restoration program

Arabian Peninsula: Islamic Archaeology, Fig. 3 Zubarah fort during National Day 2008. The site has national significance and is used as a location for heritage reenactments. To the south of the fort are extensive ruins of the city of Zubarah which are currently being excavated and restored

Arabian Peninsula: Islamic Archaeology, Fig. 4 Julfar ware jar in al-Khaimah museum. Julfar ware was produced from the medieval period until recent times and was widely used in the region of the Gulf

Theoretical Approaches

As a branch of archaeology which focuses on a historical period, Islamic archaeology can benefit from many of the theoretical and practical perspectives of historical archaeology as it has developed in Europe and the Americas. Particular importance can be attached to issues of globalization in which Arabia, as the bridge between the Mediterranean and the Indian Ocean worlds, was a key component. Also of interest is the diffusion of crops such as coffee from Arabia to the Americas as well as the importation of tobacco (see, e.g., Bouzigard and Saidel 2012). In the future it is likely that these approaches will demonstrate that Arabia was already a major component of world trade systems before the discovery and exploitation of oil.

Archaeobotany

Dorian Q. Fuller and Leilani Lucas
Institute of Archaeology, University College London, London, UK

Introduction and Definition

Archaeobotany is a composite discipline, combining botanical knowledge with archaeological materials. Archaeobotany is also known as *palaeoethnobotany* (or *paleoethnobotany*). It focuses on the study of preserved plant evidence from archaeological sites and the reconstruction and interpretation of past human-plant relationships. The term "archaeobotany" emphasizes the archaeological nature of the evidence, with its recognition of site formation processes and sampling issues. The term *paleoethnobotany*, especially prominent in North America, recognizes the importance of modern ethnobotanical studies in contributing to interpretations of the past. This needs to be kept distinct from the term *palaeobotany*, which is the study of past plants, their adaptations, evolutionary relationships, and communities, from the fragmented remains that are preserved in old sediments. While palaeobotany takes in the whole history of plant life on land (approximately 415 Ma), archaeobotany focuses on the plant evidence relating to past human environments of the Pleistocene and Holocene.

Like many other specialist subdisciplines of archaeology, archaeobotany has evolved from a side-line pursuit of scientists outside of archaeology to something that is very much a part of archaeological research (for histories, see Hastorf 1999, Pearsall 2000, and Fuller 2008). The origins of this field of research can be traced back to the nineteenth century, especially to a prominent expert on fossil plants, Oswald Heer, who carried out the first studies of archaeological plant remains recovered from waterlogged Swiss Neolithic and Bronze Age lake-side sites. His detailed monograph on these, in 1865, had a major impact on the discipline of archaeology and the early development of evolutionary biology; see by extension, summaries in Charles Darwin's *Variation in Animals and Plants under Domestication* (1868) and John Lubbock's *Prehistoric Times* (1872), which introduced to archaeology the term "Neolithic." For much of the subsequent century, recovered plant remains were sent by archaeologists to botanists for study, for instance, specialists working at natural history museums. However, specialist archaeobotanists taking part in archaeological fieldwork only began to be staples of archaeological research from the 1960s onward. Particularly important for this trend was the advent of improved systematic sampling of plant remains through the flotation method, first carried out in the USA and the Middle East in the 1960s. Flotation, a key method in archaeobotanical research, uses water to separate light organic remains (especially charcoal and carbonized seeds) from heavier archaeological material and the sand component of sediment (details of various systems in Pearsall 2000).

Key Issues/Current Debates

Research Themes

In general terms, archaeobotanical research questions relate to both past food-related practices/foodways, and past landscapes. A central concern of archaeobotany is the recovery of evidence for food plants exploited by past populations, where these plants came from, and how they were processed. In the study of hunter-gatherer societies, there are often challenges of preservation; yet, research on plant subsistence is crucial to examining issues of seasonal scheduling of activities, intensification of plant use and processing, storage, and niche construction (e.g., Mason and

Hather 2002 and Wollstonecroft 2011). Another major focus of archaeobotany is the transition to, and spread of, agriculture, including research on cultivation systems, arable weeds, and plant domestication traits (e.g., Fuller 2007 and Piperno 2011). In contexts where agriculture existed, archaeobotanical research focuses on issues of diversification and intensification of agricultural systems and the organization of production and consumption of crops in relation to social hierarchy (e.g., Gumerman 1997 and Fuller and Stevens 2009). When it comes to landscapes, archaeobotany has contributed to the reconstruction of past environments as well as to studies of environmental change due to climate change and/or human impact. In this area, wood charcoal, on-site and off-site palynology, and phytolith studies are especially prominent.

Archaeobotanical Datasets and Subfields

Given that the various datasets define subfields of the discipline, few archaeobotanists practice research on all lines of plant evidence. Macroremains analyses tend to focus on the study of seeds only, whereas wood charcoal and the analyses of phytoliths and starches are specializations in their own right. Still these various datasets are largely complementary and gain strength from integration. The sections below, and Table 1, summarize the main lines of archaeobotanical evidence and their respective potentials. The study of Palaeofaeces, i.e., the analysis of exceptionally preserved human coprolites and gut contents, is

Archaeobotany, Table 1 Archaeobotanical datasets, preservation environments, and typical spatial resolution

Data sets:	Preservation	Spatial resolution (typically)
Macros: remains of seeds and other fruit fragments	Charred	Local, biased by human procurement
	Waterlogged	
	Desiccated	
	Mineralized	
Macros: wood charcoal	Charred	Local, biased by human procurement
	Desiccated	
	Waterlogged	
Macros: parenchyma fragments	Charred	Local, biased by human procurement
	(Potentially desiccated)	
Plant impressions in pottery/ mud-brick	In pottery or hardened clay, therefore all environments where pottery or mud-brick is used	Local or nonlocal (traded), biased by human procurement and tempering preferences
Pollen	Fine sediments, especially acidic (alkaline and oxidizing conditions destroy pollen)	Regional
Phytoliths	Fine sediments, minimal bioturbation (of most pH levels except very high alkalinity (>9) and high temperatures).	Local plant use activities (on-site)
		Regional vegetation (when part of off-site studies, as with pollen)
Starch Grains	Preserved in dental calculus	Components of human/ animal diet
	From artifact surfaces (groundstone, ceramics)	Plant parts and taxa processed on these tools or vessels
Palaeofaeces (i.e., preserved feces or coprolites, and gut contents from mummies or bog bodies)	Mineralized	Local diet, but may contain regional pollen
	Waterlogged	
Diatoms are sometimes examined in archaeobotanical research		Regional aquatic environment

another source of archaeobotanical data that may combine several lines of evidence (Hillman 1986).

Macro-Remains: Crops, Chaff, and Weeds

Macro-remains refers to plant remains that are visible to the naked eye (larger than 0.25 mm), but which still require microscopy to identify. Seeds, which are the most common evidence studied by archaeobotanists, can be preserved by numerous means, including mineralization, waterlogging, metal oxide preservation (sometimes called pseudomorphs), or as impressions in pottery. The most common means of seed preservation encountered, however, are charred seed remains. Generally, charred macro-remains can be identified by examination of their external morphology through a low powered binocular microscope (i.e., 6x–40x). It has now become possible to extract fragmentary ancient genetic information (i.e., aDNA) from ancient seeds, and the prospects of this technique are immense (Palmer et al. 2012).

In general, charred assemblages sample only a very limited range of the floristic diversity of local flora. This came to be recognized in Europe in the 1970s. It was observed that most archaeobotanical samples consisted of a similar range of taxa that are dominated by grain crops (seeds and chaff) and wild species known from modern field studies as weeds of cultivation or weeds of habitats that are disturbed by humans (Jones 1985). However, by far, the best represented remains were those of cereals, in part due to the good preservation of grain and chaff. Thus, aside from the remains of a few wild fruits likely collected for food, most of this fossil evidence can be interpreted as deriving from arable plant communities rather than the environment at large. Therefore, the associations of grains, chaff, and weed seeds can be used to infer aspects of crop-processing (Hillman 1984; Jones 1987; Fuller and Stevens 2009). After crops are harvested, they must be processed in predictable ways, to remove inedible husk (and weeds) and to separate the grain products. Through ethnographic studies, archaeobotanists have developed predictive models about sample composition, which allow the stages of crop-processing represented to be inferred. Most studies have been on the crop-processing of Mediterranean wheat and barley (e.g., Fuller and Stevens 2009), but one can also find studies of millets (e.g., Reddy 1997; D'Andrea and Wadge 2011), rice (Thompson 1996), and some new world crops (e.g. Lopez et al. 2011). These ethnoarchaeological models have made it possible to interpret crop-processing, which can be divided into two basic sets of activities: those that break apart the crop-plant and those that separate out the various freed components. The first activity includes threshing to break apart cereal ears, or separate the pods of some pulses. Another later stage, for hulled crops, is de-husking, which removes the hulls and glumes that are still attached to the grain. In simplified terms, the early stages produce waste that is rich in chaff (especially of free-threshing cereals, like bread wheat and barley) and weed seeds, especially smaller, lighter weed seeds that are removed by winnowing. Later stages will have a higher proportion of grains, fewer weeds that are generally larger and heavier, and will only have chaff from hulled cereals (like the glumes of emmer or einkorn wheat).

Parenchyma, the starchy storage tissue of plants, which predominates in tubers and other underground storage organs, can also be preserved by charring. Such material has not traditionally been searched for in archaeobotanical samples, but studies from a number of regions have found it to be fairly common among seeds and charcoal (Hather 2000), and this line of evidence has the potential for identification of wild or cultivated roots and tubers. This approach should be an important part of research on the origins and development of Vegeculture. Identifications of this material requires the high magnifications and depth of field provided by scanning electron microscopy (SEM).

Macro-Remains: Impressions

Another source of evidence of seeds and chaff is preserved impressions of plants. Plant impressions, often preserved in pottery, are one of the traditional sources of archaeobotanical information. However, today, the study of impressions is

often eschewed when charred remains recovered through flotation are available from a site. Impressions can be studied at lower magnifications and often latex casts are prepared from the molds, which can then be analyzed by SEM. Most cereal parts, such as chaff, are preserved in pottery since these readily available by-products of grain production were often used for tempering pottery. In some cases, this provides early evidence for crop domestication, such as in West Africa (e.g. Manning et al. 2011).

Macro-Remains Wood Charcoal

Wood charcoal is the most abundant component of archaeobotanical flotation samples. Given the centrality of fire in human cultures, wood charcoal is among the most abundant of cultural by-products. In contrast to seed remains, which represent chance/incidental burning, wood is generally considered to be the product of intentional burning. Wood can also be preserved under other circumstances, such as waterlogging. It is identified by looking at anatomical characters in transverse, tangential, and radial sections. This kind of study requires higher magnifications, generally 50x–150x, but sometimes as high as 400x, and beyond, which is aided by SEM. Since most fuel is likely to come from the vicinity of the site, it should provide some reflection of the surrounding vegetation. Numerous studies have utilized changes in the composition of wood taxa to examine changes in the landscape, but fuel choice may also reflect social and political concerns (Asouti and Austin 2005; Marston 2009).

Micro-Remains: Phytoliths, Starch, and Pollen

There are a number of lines of archaeobotanical evidence that are beyond the range of human vision and must be extracted from sediment samples, mounted on slides, and examined under high magnification. These lines of evidence are micro-remains, and include phytoliths, pollen, and starch grains. The most widely studied micro-remains in archaeology are phytoliths (sometimes called "plant opals," silica skeletons, or spodograms), which are the silica casts of plant cells formed by the evaporation of silica-laden water through plant transpiration (Pearsall 2000). Being an inorganic glass, these have a high potential for preservation in many sedimentary environments, although they are likely to be destroyed by mechanical processes. The study of these remains requires magnifications from 200x to 1,000x. Phytoliths are invisible in cross-polarized light. Phytolith identification is complicated by the fact that any given plant produces numerous different forms of phytoliths and similar phytoliths forms may be produced by unrelated species. Nevertheless, some phytolith forms are diagnostic. Because of the high preservation potential of phytoliths, they have proved particularly important for examining plant exploitation prior to agriculture in the Palaeolithic (Madella and Jones 2002), and for tracking crops in tropical environments with poor on-site preservation of macro-remains (e.g., Piperno 2011).

A more recently expanding line of research are starch grains; the intracellular storage of starch by plants. The form of starch grains appears to be taxonomically determined, allowing separation of families, and sometimes genera and species (Torrence and Barton 2006). There also seems to be some indication of domestication in some taxa (e.g., Piperno 2011). Most often starch grains are extracted from the surfaces or residues of artifacts, such as groundstone, but they also become trapped in dental calculus and, as such, reflect human diet. Starch grains have been central to the archaeological study of past Chimpanzee archaeology (Mercader et al. 2007). Some traditional archaeobotanists still regard starch grains with suspicion and there is on-going research and debate on issues of taphonomy, preservation, and identification, as there is with other lines of archaeobotanical evidence.

Pollen is usually collected from off-site geological sediments (palynology) for examining palaeoecology, which is often of relevance for archaeological interpretations. Of particular interest are approaches to identifying the introduction or intensification of agriculture through pollen. In addition, pollen is sometimes preserved in archaeological sediments (archaeological palynology), which can help fill-out reconstructions of past

vegetation (e.g., Dimbleby 1985 and Pearsall 2000). Pollen is studied at similar high magnifications as phytoliths.

International Perspectives and Future Directions

The growth of archaeobotany has been uneven internationally. As reviewed in Fuller (2008), several regions of the Old World have seen different chronologies for the development of this field. It was earliest in Europe, quite early but small-scale in India, and early in the Near East. Development in Africa has been slow, and the majority of sub-Saharan countries have had no archaeobotanical research. The USA has a long tradition of archaeobotanical research, but for much of the Neotropics, developments have been more recent and are spatially uneven (cf. Piperno 2011). Japan has had a longer tradition of studying waterlogged macro-remains, using flotation, and undertaking phytolith research, whereas such developments are quite recent in China or Korea. Most of Southeast Asia is un-sampled and understudied (Castillo and Fuller 2010). Thus, while archaeobotany has potential application anywhere – all human societies have used and consumed plants – its adoption has been uneven, partly biased toward countries with better funded research institutions and partly focused on regions deemed to be centers of origins of agriculture and civilization (e.g., Mesoamerica or Southwest Asia). Archaeobotany has greatly expanded internationally and across a range of subfields. It is set to continue to do so in the future.

Archaeobotany of Agricultural Intensification

Meriel McClatchie
School of Archaeology, University College Dublin, Dublin, Republic of Ireland

Introduction

Although agriculture was introduced into Europe at the beginning of the Neolithic period, archaeological studies often suggest that intensive systems of agricultural production were not practiced until the Bronze Age. In the case of Ireland and Britain, for example, the increased appearance of archaeologically identifiable fields and farmsteads during the Bronze Age is often understood to represent agricultural intensification (see Brück 2000: 275). The intensification of agriculture in Bronze Age Europe is of enormous significance, as it is considered to be a precursor to increasing social stratification, with the creation of a strong agricultural economic base enabling the development of hierarchies that controlled the means of production and distribution of produce. This model of increasing intensity over time will be challenged here through detailed consideration of agricultural terminology and archaeological evidence for intensification, with a focus on archaeobotany and Ireland. It will be shown that intensification represents just one of many agricultural strategies available to prehistoric farmers in Europe and cautions against an

overfocus by archaeologists on this mode of production.

Definition

The definition of intensification used by many archaeologists worldwide is derived from the seminal work of a Danish economist, Ester Boserup, who published a revolutionary study in 1965 entitled *The Conditions of Agricultural Growth*. Boserup's study proposed a model for the development of intensification in non-industrial farming societies. Since the publication of her work, the validity of Boserup's model has been much debated, mainly among ethnographers, but also in other disciplines such as agronomy, history, and, to some extent, archaeology. It appears, however, that many archaeologists have not followed these subsequent debates, while others are misinterpreting the basic meaning of intensification.

There is a need for more precision in terminology used to describe agricultural systems. In archaeological studies, the term "intensification" is sometimes used to refer to an increase in production or increased detection of remains (Morrison 1994, 1996: 587). The definition of intensification will be taken as follows: intensification is an increase in labor and/or capital inputs to a fixed area of land in order to increase or maintain production (after Brookfield 1972: 31). Intensification aims to achieve not simply an increase in overall production; instead it aims to increase productivity per unit of land.

Land capital remains the same in this process, in that the area of land being farmed does not increase; the increase is in labor and/or capital inputs with the aim of increasing or maintaining production. While labor inputs can be applied at a specific point in time, capital inputs – including the construction of terracing, irrigation, and field systems – may have to be created before they can be used, perhaps over a long period and then enduring for a substantial period of time (Brookfield 1972: 32).

If the goal is to increase productivity through the cultivation of a greater area of land than previously farmed, then this process is known as "extensification" rather than intensification. Extensification can take place when people move out over the landscape – thereby extending the area of land being farmed – rather than increasing inputs into a fixed area. Extensive farming is often characterized by a lower level of input and lower output per unit area, but a higher output per capita (van der Veen 2005: 158).

Historical Background

Boserup's model of agricultural intensification, *The Conditions of Agricultural Growth* (1965), is one of the most influential formulations of this issue from the last century. Based on ethnographic work, Boserup argued that an increase in population density was responsible for an increase in the intensity of cultivation. Boserup proposed that in preindustrial societies, as farmers intensify agricultural production, cultivation systems pass through a universal and linear sequence of evolutionary stages. According to this model, a clear trajectory of agricultural development can therefore be identified.

Boserup suggested that extensive forms of shifting cultivation gradually become more intensive by a reduction of the fallow length. According to this model, shifting cultivation might take place in order to minimize the possibility of soil exhaustion – land is cultivated and then abandoned in order to leave it fallow and allow the soil to regenerate, whereupon the land can be farmed again at a later time. With more intensive strategies, Boserup suggested that communities reduce the length of time that the ground is left fallow. Communities are able to reduce the fallow length by introducing more labor and/or capital until they eventually reach the stage of annual cropping or even multicropping. Increased labor will allow more tillage and seedbed preparation, as well as more weeding, all of which can encourage reduced fallow periods. Capital inputs can include the use of superior tools and increased diversity in crops. Boserup also refers to inputs such as manuring and the enclosing of land in the progression toward intensification.

Many of Boserup's stages can be identified archaeologically, for example, in the form of

innovative tools, soil modifications, and field boundaries. It is likely that the ability to identify these stages has influenced the popularity of Boserup's model in archaeological studies. The model appears to be straightforward – people start out by farming extensively with low inputs, progressing toward more intensive farming by adding in more labor, tools, and various other methods to increase or maintain productivity in an area of land. Boserup's assertion that population pressure was a causal factor in encouraging intensity of agricultural production has also found favor among archaeologists, as it has often been suggested that population pressure was a causal factor leading to societal and economic changes in Bronze Age Europe (Sherratt 1981).

Since the publication of *The Conditions of Agricultural Growth*, there have been many criticisms of this model of agricultural intensification and also of its application uncritically by archaeologists (Brookfield 1984, 2001; Kirch 1994; Morrison 1994, 1996; van der Veen 2005). Boserup did, however, provide a very useful framework for highlighting some of the many variables in the process of agricultural change, and this seminal study resulted in much discussion and development of these complex issues as they pertain to different societies and environments throughout the world.

Key Issues/Current Debates

Does Agriculture Evolve from Extensive to Intensive Systems?

One of the main debates in agricultural intensification relates to the concept of unilinear progression, whereby agriculture is considered to start out as extensive and then becomes increasingly intensive as time progresses. Boserup (1965) proposed an evolutionary continuum toward fixed field-intensive agriculture, which argued for a clear trajectory from extensive to intensive farming. Diversity and variability are, however, critical aspects of both the structure of agricultural production and the process of agricultural intensification. Extensive and intensive forms of cultivation are different options, rather than stages of an evolutionary sequence. They represent strategies available to farmers to choose from, depending on local, social, and economic circumstances and to use alongside other strategies such as innovation, specialization, and diversification (van der Veen 2005: 158). Intensification should therefore be viewed as consisting of one of multiple potential strategies, rather than a single process.

A consequence of this view is that there may be multiple paths or courses toward intensification rather than a single route from shifting to fixed agriculture, from extensive to intensive production, and from long to short fallows (Morrison 1994: 115). The direction, as well as the rate, of change may have varied, depending on economic and cultural circumstances at different times and places, with the possibility of reversals occurring, whereby agriculture became more or less intensive. Boserup's model suggested that early farmers would have made use of shifting agriculture, eventually moving toward fixed plot, more intensive agriculture. This model was applied by archaeologists to Neolithic societies in Europe, where it was assumed that extensive agricultural practice eventually gave way to more intensive systems in the Bronze Age. The archaeobotanical evidence from Neolithic Europe does not, however, support this application of Boserup's model.

Bogaard's (2002) study of early crop husbandry in Central Europe investigated management of agricultural plots through analysis of ecological characteristics of potential arable weeds. Ecological characteristics relevant to the permanence of cultivation plots were previously determined during the "Hambach Forest experiment" in Germany, where experimental plots on loess soils, cleared of long-lived deciduous woodland, were cultivated over a 6-year period and surveyed immediately prior to harvest time in order to document the weed flora. It emerged that arable weed flora associated with recently cleared plots managed with little or no tillage and weeding (as in a shifting cultivation regime) is likely to be dominated by perennial taxa, particularly woodland perennials. Dominance by annual taxa is more likely to be indicative of long-established cultivation plots on regularly

disturbed soils (representing a more intensive regime). Bogaard's analysis of archaeobotanical weed data from sites in the western loess belt and Alpine foreland demonstrated that many Neolithic cultivation plots in these regions tended to be long established, rather than temporary, plots, suggesting that shifting agriculture was not taking place. Bogaard, together with Jones, also applied this approach to weed assemblages from Neolithic Britain, where they found further evidence for weeds associated with more intensive and long-term cultivation strategies in archaeological deposits associated with the earliest farmers (Bogaard and Jones 2007).

The difficulties in directly applying Boserup's model, which is based upon tropical agricultural systems, to temperate agricultural systems, such as Europe, have been highlighted (e.g., Sherratt 1981: 290). It could be argued that shifting cultivation is an agricultural system adapted to a specific set of ecological circumstances – found primarily in the humid inner tropics – to ensure maintenance of soil fertility. The application of such a system to Europe may be inappropriate, because different soil types and the presence of domestic animals enabled different forms of soil nutrient restoration in this region (Sherratt 1981; van der Veen 2005: 157).

Population Change and Intensification

Potential relationships between agricultural intensification and population change represent another issue that has been much debated. Population pressure has often been regarded as a causal factor leading to societal and economic change in Bronze Age Europe (Sherratt 1981). Boserup (1965) argued that population pressure was the primary causal factor of intensification – more intensive agricultural strategies can support increasing populations, with intensification in turn requiring increased labor per unit of food produced.

Boserup suggested that intensification in food production originated as a response to factors beyond human control, in that humans were unable to prevent population increase. Anthropological studies have, however, revealed numerous examples of birth-spacing practices, abortion, and infanticide, suggesting that population increase has been subject to human intervention throughout prehistory (Kirch 1994: 310). More importantly, population growth and resultant land shortages are not in all cases the primary inducements for intensification. Demographic factors can be of variable importance in different cases, and intensification is not the only response to land shortage (Stone 1994: 317; Stone and Downum 1999: 115). Other responses could include migration, conflict, and changes to nonagricultural enterprises, while coercive social relations, such as chiefdoms, may also influence intensification. There is also the issue of which came first – was population increase followed by changes in agricultural practice or could populations have expanded *following* "favorable" circumstances, for example, where there was a stable agricultural base to support more people?

It has been argued that the disadvantages associated with intensive agriculture ensure that such modes of production will be adopted only when necessary, citing disadvantages such as increased labor inputs and declining efficiency of that labor over time (Boserup 1965). Diminishing returns on labor are assumed, which results in declining efficiency as intensification increases. Efficiency considerations can, however, be overridden, and an increase in production does not always correspond to a decline in efficiency (Stone and Downum 1999). Efficiency can vary according to the types of crops grown – e.g., hulled versus naked crops and spring-sown versus autumn-sown crops – and methods of cultivation. As well as technical innovations – such as new tools – social innovations can be hugely significant, including mobilization of labor, increases in productivity of labor, and improvements in the management of resources. Efficiency in time management, for example, rather than basic labor input, can be of significant importance – there can be major differences in productivity between adjacent farms that are similar in workforce endowment (Brookfield 2001: 184).

It has also been argued that agricultural producers exerted the minimum effort required to meet their needs – the Law of Least Effort (Boserup 1965). In this way, people and societies

make rational, informed choices in order to maximize the outcome of agricultural activities in the local landscape. But were agricultural strategies in Bronze Age Europe focused on maximization of production? As well as providing calorific value, crops can also be grown for social returns, being used, for example, in ceremonial and "ritual" activities. Ethnographic evidence indicates that inputs may appear uneconomic when measured against calorific returns yet reasonable when measured against social returns (Brookfield 1972: 38). Intensive production should not, therefore, automatically be assumed to be an objective in Bronze Age Europe.

International Perspectives

Were the Earliest Farmers in Ireland Engaged in Intensive Agriculture?

Arable agriculture was introduced into Ireland in the centuries after 4000 cal BCE, and it has often been suggested that the earliest farming was extensive, with intensive practices becoming more widespread during the Bronze Age (2500–600 cal BCE). This assumption is based presumably on the Boserupian model, which suggests that agricultural production would have started out in an extensive manner, eventually becoming more intensive. The relatively large quantity of cultivated archaeobotanical remains from Bronze Age sites in Ireland, when compared with Neolithic sites, is also likely to have been of influence. This evidence does not, however, necessarily mean that more intensive practices were being undertaken during the later period – increased production does not automatically mean intensification. It has been shown above that the evolutionary model of agricultural production – whereby systems progress from extensive to intensive – is not appropriate in many cases. A better method of assessing the intensity of farming practices in Neolithic Ireland is through ecological analysis of potential arable weeds.

The contribution of arable weed analysis in detecting intensity of agricultural production has already been discussed above, with reference to archaeobotanical studies from Central Europe and Britain. Previous studies have established the types of arable weeds characteristic of a shifting cultivation regime versus arable weeds more associated with long-established cultivation, representing a more intensive regime. Analyses of arable weeds from Neolithic sites in Central Europe and Britain have indicated that cultivation plots in these regions tended to be long established, rather than temporary, suggesting that shifting agriculture was not taking place (Bogaard 2002; Bogaard and Jones 2007). This approach has recently been applied to archaeobotanical data from Ireland for the first time, and a similar picture is emerging (McClatchie et al. 2014). Although the Irish Neolithic dataset is smaller than that from Britain or Central Europe, it appears to follow a similar trend, in that disturbed weed taxa are dominant and woodland taxa are rare, while annual species are more commonly recorded than perennial species. In common with Neolithic Britain and Central Europe, the evidence from Ireland does not resemble the picture expected for newly cleared plots managed under a shifting cultivation regime. The earliest farmers in Ireland instead appear to be engaged in more intensive practices than previously acknowledged. More detailed investigations into functional weed ecology can shed further light on cultivation intensity, distinguishing between arable weeds growing on intensive "garden" plots and extensive "field" cultivation (Bogaard et al. 2016).

Do Prehistoric Field Systems in Ireland Represent Intensification?

It has been noted above that an increased appearance of archaeologically identifiable fields has been interpreted as representing agricultural intensification in prehistoric Europe. The construction of field systems creates both enclosures and boundaries. The enclosing of land can be effective in the prevention of further soil erosion, particularly on sloping ground, because it can help decelerate soil creep and encourage drainage. Boundaries can protect animals and crops by preventing wind chill and providing shelter. As well as enclosing and bounding areas of land, the

construction of field systems is also a form of *landesque* – investing in the land beyond the life of the current crop (Brookfield 1984).

One of the earliest, and indeed largest, examples of field systems from prehistoric Europe can be found at the Céide Fields, County Mayo, on the northwest coast of Ireland. Here, well-defined rectangular field systems, consisting of stone walls, were erected over an area of approximately 12 km^2 around the middle of the fourth millennium BCE and then covered by peat growth, thus enabling their preservation (Caulfield 1978; Figs. 1 and 2). The fields appear to be large in size and are often thought to have enclosed animals, although it should be noted that organic hedge boundaries, which would have left little trace, could also have been used to subdivide fields for arable use. While this early evidence from the Céide Fields is certainly significant, prehistoric field systems in Northwest Europe more often date to the Bronze Age, as is the case in Ireland. Some field systems appear to have an orderly layout – for example, at the Céide Fields – while others tend not to be laid out in a coaxial manner, instead being less regular in their arrangement, perhaps indicating more gradual and incremental growth.

The erection of agricultural walls, dams, irrigation features, and terraces can require a substantial labor input in their construction and maintenance, which is sometimes interpreted as evidence for intensification. Although it is clear that the increase in field systems during the Bronze Age represents a change in the organization of production, this does not necessarily imply any enhancement in productivity. Studies of field systems often focus on morphology of the fields as well as economic and technological aspects of their construction and use. The increased appearance of field systems may also reflect changing

Archaeobotany of Agricultural Intensification, Fig. 1 Aerial view of a section of the Céide Fields, County Mayo, Ireland – prehistoric stone walls. (Courtesy of Photographic Unit, National Monuments Service, Department of Culture, Heritage and the Gaeltacht)

Archaeobotany of Agricultural Intensification, Fig. 2 Section of the Céide Fields, County Mayo, Ireland – prehistoric stone walls

social relationships between people and landscapes, rather than being explained solely in economic or technological terms. Field boundaries can be established for reasons other than increasing productivity of the land (Stone 1994; Brück 2000). Field boundaries can be constructed to mark boundaries – to transmit information – and also to protect boundaries or control access. Field boundaries will therefore not *necessarily* occur where cultivation is intensive. It is also worth noting that landscapes can be demarcated conceptually and their natural features can convey symbolic meanings, without the land itself being altered in any way by field boundaries, ditches, lines, or posts (Bayliss-Smith and Golson 1999: 209). So while field boundaries may well be part of an intensive system, their presence does not automatically imply intensification. Field boundaries may even be part of an extensive strategy, whereby people are moving out over the landscape. It seems, therefore, that a variety of economic and social strategies might have prompted the increased construction of field systems in Bronze Age Ireland. This may be better understood as a *transformation* in the way that agriculture was being carried out.

An alternative means of determining the intensity or otherwise of agricultural production is through geoarchaeological analysis of the sediments themselves. Manures can be important indicators for the intensification of arable production, because they are an example of applying increased inputs to a fixed area to increase/maintain production. Such soil amendment strategies have been detected at the Bronze Age field system in Belderg Beg, County Mayo, through geoarchaeological analyses (Verrill and Tipping 2010). Another recently developed technique is the investigation of manuring through analysis of stable isotope values in cereal remains, specifically $\sigma^{15}N$ values. Investigations of modern crops have shown that manuring with animal dung has a clear effect on stable nitrogen isotope ratios in cereals, and this can be measured to reveal distinct local or regional strategies in the use of manures (Bogaard et al. 2013). Furthermore, combining crop stable isotope ratios with functional weed ecology can be very effective in identifying cultivation intensity (Bogaard et al. 2016). A variety of methods can therefore be employed to explore intensity of cultivation at an individual site.

Future Directions

It is clear that the causes and paths of agricultural change can be complex – variability and diversity are often evident in the archaeological record. Intensification is not caused by any single factor, such as population pressure. It may instead be influenced by a variety of demographic, social, and economic factors. There is not an evolutionary trajectory in all agricultural systems, whereby they go from extensive to intensive farming. Similarly, certain landscape features do not automatically imply any individual agricultural strategy – it has been demonstrated above that the construction of field systems is not always indicative of intensive agricultural production. The term "intensification" and its implications have, unfortunately, been misused and misunderstood in some archaeological studies. Future studies should aim to pay more attention to the use of proper terminology and to be more critical when exploring evidence for agricultural change – in the case of prehistoric Europe, it could be argued that the problem with Boserup's model is not so much the model itself, rather the way it has been applied and oversimplified by others. While the identification of true intensification in the archaeological record can certainly be challenging, a variety of useful environmental analyses are now available, including geoarchaeological and isotope studies. Investigation of archaeobotanical evidence – such as arable weeds – can also provide new insights into the intensity or otherwise of land use. More frequent use of such methods is recommended. Archaeologists should, however, be careful not to overfocus on trying to identify intensification in the archaeological record. Depending on local circumstances, different agricultural strategies may have been deployed at different times and in different places, with the possibility of co-occurrence. It may be more worthwhile to explore the potential for a variety of different

strategies, which may include intensification but also includes other options such as innovation, specialization, and diversification.

Archaeobotany of Early Agriculture: Macrobotany

Rob Cuthrell
Department of Anthropology, University of California, Berkeley, CA, USA

Introduction

Analysis of archaeological macrobotanical remains continues to be a primary source of direct evidence for the development of agriculture in many parts of the world. Macrobotanical remains are small in size, often fragile, and require special conditions for preservation, making interpretation of archaeobotanical assemblages a complex process. There are multiple ways that macrobotanical remains can be used to explore early agriculture and plant domestication, from techniques examining morphological changes in seeds to statistical analysis of changes in archaeobotanical assemblages. Recently, archaeobotanical evidence in multiple parts of the world has been used to argue for extended periods of "predomestication cultivation" in early agricultural systems.

Definition

Macrobotanical remains are archaeological plant remains that are large enough to be seen with the naked eye. These remains usually range in size from several centimeters (e.g., wood charcoal and tubers) down to 250 μm (e.g., very small seeds). Using stereomicroscopes, archaeobotanists examine these remains for diagnostic features that can be used to identify the plant to the lowest taxonomic level possible (e.g., genus or species). Morphological and morphometric studies are also often carried out on macrobotanical remains from early agricultural sites to examine changes resulting from plant domestication. Although macrobotanical remains can include items such as wood charcoal, herbaceous plant material, and parenchyma, in the context of early agriculture the focus of research is usually on the seeds of cultivated or domesticated plants.

Key Issues

The Nature of Macrobotanical Research in the Context of Early Agriculture

Although microbotanical remains such as silica phytoliths and starch grains have recently demonstrated some of the earliest evidence for agriculture in some parts of the world (e.g., in the New World Neotropics and Southeast Asia), macrobotanical remains continue to be the primary source of evidence for most archaeobotanists who study the development of plant cultivation and agriculture worldwide. Macrobotanical research, though often challenging, is particularly

valuable because it allows researchers to directly investigate relationships between people and plants (Pearsall 2010: 247). By using strict methodological controls and statistical measures recording changes in seed morphology, taxon abundance, and assemblage diversity through time, archaeologists can use macrobotanical remains to detect shifts in plant use practices that are not discernable through the analysis of any other type of archaeological remains.

Unlike mineralized artifacts such as ceramics and bone, macrobotanical remains require special conditions for preservation and special techniques for recovery. Carbonization transforms botanical matter into compounds that cannot be broken down and consumed by living organisms, such as insects and microbes. With the exception of dry, waterlogged (anaerobic), or frozen conditions, carbonization is usually required for botanical preservation at archaeological sites. The majority of botanical evidence for early agriculture comes from such charred macrobotanical remains, with some exceptions. For example, Grobman et al. (2012) recovered numerous partially charred and uncharred remains of maize (*Zea mays*) from a desert site on the north coast of Peru from layers dated c. 6700–5000 BP, and some of the earliest evidence for rice agriculture in central China comes from waterlogged levels at the Hemudu site, dated c. 7000–5800 BP (Zhao 2011).

Although macrobotanical remains can include relatively large materials such as charcoal and tubers, most macrobotanical remains are small and thus unlikely to be recovered through typical dry screening. The development and spread of the flotation recovery method in the 1960s allowed the recovery of representative archaeobotanical assemblages and were responsible in large part for the development of archaeobotany as an archaeological subdiscipline (Pearsall 2010). In flotation, archaeological sediments are disaggretated in a water-filled tank, allowing charred botanical remains to float to the surface of the water for collection in fine mesh sieves.

The requirement of carbonization acts as a preservation filter for macrobotanical remains, with important implications for the interpretation of archaeobotanical assemblages. Plants that are processed, consumed, and discarded in the absence of fire (e.g., many fruits) are unlikely to be preserved in the archaeological record, while those that are exposed to fire are more likely to dominate archaeobotanical assemblages. In the context of early agriculture, this can lead to ambiguities in the interpretation of wild and domesticated plant use, particularly in cases where dung may have been an important source of fuel. For example, Miller (1996) argued that the archaeobotanical assemblage at early Abu Hureyra (c. 11,000 BP), which contained a broad range of seed taxa, including seeds which are inedible to humans without processing, was not just the result of crop processing but also of dung fuel use, however, Hillman et al. (1997) suggested that the assemblage of wild plant taxa was instead a reflection of the broad-based seed collection strategy practiced by site inhabitants.

In any agricultural site, the sequence and location of crop processing activities shapes the archaeobotanical assemblage. Heuristic models of pathways to botanical preservation (i.e., formation processes), often based on ethnoarchaeological studies, are required to accurately reconstruct past practices (Fuller and Weber 2005). These models should integrate how and where crops are harvested, threshed, winnowed, stored, ground, cooked, consumed, and discarded, as well as how taphonomic processes affect the distribution and preservation of remains after deposition (Fuller and Weber 2005). Variations in crop processing sequences between sites and time periods preclude simple comparisons of macrobotanical assemblages across time and space. The proportion of agricultural weeds may be much higher at one site than another, but this pattern could result from increased exposure of winnowed botanical materials to fire or the use of dung as fuel rather than co-consumption of arable weeds with agricultural crops.

The process of carbonization also affects the morphology of plant seeds. Seeds with hard testas or fruits with stony endocarps tend to retain their shapes during carbonization, while seeds and fruits lacking hard testas and containing large quantities of starch (e.g., grass caryopses) or oils

(e.g., flax seeds) often exhibit dramatic changes in morphology and appearance after carbonization. Märkle and Rösch (2008) documented significant differences in the environmental requirements (temperature, duration, and oxygen availability) for preservation through carbonization between cereals and oily seeds, showing that oily seeds are much less likely to be preserved than cereals in oxidizing conditions. Thus, interpretation of archaeobotanical assemblages must also take into account the different conditions necessary for preservation. The absence of a taxon in an archaeobotanical assemblage does not necessarily imply that it was not present or in use at a site.

Macrobotanical Remains as Evidence for Cultivation and Domestication

Evidence for early agriculture is drawn from multiple lines of evidence, including the development of novel tilling/harvesting/processing technologies, increased sedentism, changes in isotopic indicators of dietary composition, and many others. However, often the most direct form of evidence for early agriculture has come from the detection of domesticated characteristics in the morphology of plant seeds. Fuller (2007: 904–5) identified six phenotypic traits that comprise the "domestication syndrome" for field crops: elimination of natural seed dispersal, reduction in seed dispersal aids, increasing seed/fruit size, loss of germination inhibition, synchronous tillering and ripening, and more compact growth habits. Of these, the first four can be examined using archaeobotanical remains. One additional characteristic, parthenocarpy (fruit maturity in the absence of seed fertility), may be useful in identifying vegetatively propagated plants.

In addition to morphological attributes of seeds and fruits, characteristics in the composition and structure of archaeobotanical assemblages can also indicate plant cultivation. Examples include botanical remains found outside of their natural ranges, unexpectedly high densities of botanical remains within natural plant ranges, and changes in the maturity of seeds in assemblages.

Elimination of Natural Seed Dispersal/Reduction in Dispersal Aids

In the overwhelming majority of wild cereals, grains are connected to the rachis by a brittle attachment that shatters when the grain is mature. A small proportion of wild cereal plants exhibit nonshattering ears, a genetic mutation in which the attachments between the rachis segments are too strong to naturally dehisce. In these cereals, grains must be separated by threshing, leaving a distinct jagged attachment scar on the rachis or spikelet base (Fuller and Allaby 2009). A large proportion of nonshattering rachis fragments in an archaeobotanical assemblage provides strong evidence for domestication since seed dispersal and germination is dependent on human intervention in these contexts. Domestication also removes selection pressures maintaining plant anatomical structures that aid in seed dispersal (e.g., cereal spikelet hair cells and elongated awns), sometimes reducing or eliminating these structures (Fuller 2007).

Changes in Seed Size and Morphology

The process of domestication often results in enlarged seeds or fruits and sometimes in changes in the overall shape of these. In Near Eastern domesticated cereals, increases in seed size take the form of greater breadth and thickness in caryopses. At the site of Jerf el Ahmar in Syria, Fuller (2007) showed that the maximum breadth and thickness of both barley (*Hordeum vulgare*) and einkorn wheat (*Triticum monococcum*) caryopses increased dramatically between early (c. 11,500–10,800 BP) and late (c. 10,500 BP) occupation levels. Unlike barley and wheat, increase in rice (*Oryza sativa*) caryopsis size in central China took the form of significantly increased *length* and breadth after c. 6000 BP (Fuller 2007). Bruno (2006) argued that seed size is not sufficient to distinguish wild and domesticated forms of quinoa (*Chenopodium* spp.) taxa. Rather, morphological features such as seed coat texture, pericarp patterning, and margin configuration are required to differentiate wild from domesticated forms.

Loss of Germination Inhibition

Many wild plants produce seeds that have physical or chemical characteristics which inhibit immediate germination. Harvesting of crops in a single age cohort tends to select for seeds which germinate as soon as they are planted, reducing the incidence of germination inhibition in plant populations. This characteristic has been used primarily to identify domesticated quinoa taxa, which tend to have thinner testas than wild varieties. Bruno (2006) found that domesticated quinoa have testas 1.25–7.50 μm in thickness, while the testas of wild varieties are 11–55 μm in thickness. However, Bruno cautioned that the potential overlap between testa thicknesses between some wild and domesticated taxa makes this characteristic nondiagnostic on its own.

Parthenocarpy

Some fruit tree taxa occasionally produce parthenocarpic mutants in which fruits mature without fertile seeds. Parthenocarpic fruits can have larger quantities of sugars and carbohydrates than their fertile counterparts, making them more desirable for human consumption. Kislev et al. (2006) recovered nine apparently parthenocarpic fig fruits from the site of Gilgal I in the Jordan Valley, dated to 11,400–11,200 BP. While Kislev et al. (2006) interpreted the remains as early evidence for the horticultural propagation of fig trees, Denham (2007) argued that the parthenocarpic figs represented a small sample of specimens that may have been preferentially harvested from wild stands.

Archaeobotanical Evidence for Plants Outside Natural Ranges

The identification of domesticated or non-domesticated food plants outside of natural plant ranges can be evidence for local cultivation or for trade. Multiple lines of evidence, such as from the development of cultivation-related technologies or increased sedentism, can clarify which explanation is most likely. Weiss et al. (2006) suggested that the presence of morphologically wild lentil (*Lens orientalis*) at the site of Netiv Hagdud in the Jordan Valley around 11,000 BP indicates that soon after initial loss of seed dormancy, lentil quickly spread southward from its genetic origin in northern Syria or southeastern Turkey.

High Densities of Archaeobotanical Remains Within Natural Plant Ranges

In cases where plants used as food occur in the wild only sporadically, large quantities of the taxon on archaeological sites may indicate cultivation. Weiss et al. (2006) argued that this is the explanation for hundreds of morphologically wild lentil remains at the site of Jerf el Ahmar in Syria, dated 11,000 BP. The authors reasoned that wild lentils are unlikely to have been harvested in significant quantities due to their low abundance on the natural landscape and low seed production. They suggested that the lentil remains in the archaeobotanical assemblage represented cultigens that had lost seed dormancy, but had not yet begun to exhibit domestication-related morphological changes.

Changes in Maturity of Crop Seeds

The caryopses of wild grasses often do not mature in synchrony, but rather over a period of days to weeks. Fuller (2007), drawing on expectations of optimal foraging theory and ethnographic data, proposed that early rice harvesters could maximize wild rice (*Oryza* spp.) yields by harvesting several days after the first grains on inflorescences began to mature. At this time, many rice grains would be harvested in an immature state, creating a distinct pattern of high proportions of immature grains in archaeobotanical assemblages. Fuller (2007) argued that this pattern is evident in assemblages of early cultivated rice in central China and proposed that changes in rice morphology toward larger and plumper grains after c. 6000 BP reflect a shift toward harvesting larger proportions of mature grains.

Predomestication Cultivation and Multiple Domestication Origins

A longstanding model of domestication in the Near East proposed that founder crops were domesticated (a) relatively quickly, (b) as a package, and (c) in a single location or "core area" from which they subsequently spread (Fuller et al. 2011). This model has been called into question

through recent research. By tracking changes in the proportion of nonshattering ears and in grain sizes at early agricultural sites in the Near East, Fuller (2007) found that the period of transition from archaeobotanical assemblages comprised of wild wheats (*Triticum* spp.) and barley to those dominated by grains with domesticated characteristics was protracted, lasting up to 2000 years. Cultivation during this period, in which archaeobotanical assemblages contain both morphologically wild cultigens along with arable weeds, is termed "predomestication cultivation" and produces archaeobotanical assemblages with "semidomesticated" characteristics (Fuller 2007). Fuller et al. (2011) compared the archaeobotanical assemblages of early (c. 11,000–9000 BP) cultivation sites across the Fertile Crescent. The authors found that the suite of domesticated Near Eastern founder crops was not present at one or a few early sites in a core area. Rather, they describe domestication as occurring in a mosaic or piecemeal fashion across the region, with particular zones focusing on a limited number of early domesticates. They argue that the putative "core area" of domestication is not the origin of the Near Eastern founder crops, but rather the location of later agricultural integration of crops domesticated in multiple locations.

This pattern of multiple origins of domesticates within a region likely applies to other parts of the world as well. Smith and Yarnell (2009) reviewed evidence for the earliest domesticates in eastern North America. At each of three widely separated sites dated from c. 5000–4500 BP, only a single domesticated crop was present; evidence for an incipient "crop complex" of multiple domesticates at a single site does not appear until c. 3700 BP.

Zhao (2011) reports clear independent centers of domestication for rice and millet in central and northern China, respectively. As in the Near East, archaeobotanical data suggests a protracted period of predomestication cultivation for both crops. Zhao (2011) proposed that rice cultivation may have begun around 10,000 BP, with morphologically domesticated rice first appearing between 9000 and 7800 BP at the Jiahu site in central China. Zhao suggested that rice cultivation played a supplemental role in subsistence practices for an extended period, with full rice agriculture only beginning c. 6500 BP. Alternatively, Fuller (2011) argued that the evidence for domesticated rice at Jiahu was unclear, as archaeobotanical research at the site did not include spikelet base analysis or present clear evidence of morphological changes. Although Fuller (2011) traced the beginnings of cultivation in China to as early as c. 10,000 BP, he proposed that the earliest evidence for morphologically domesticated rice comes from the Baligang site in interior central China, dated to c. 8000 BP.

Although preliminary evidence suggests extended periods of predomestication cultivation in multiple areas of the world, the number of proto-agricultural sites examined archaeobotanically is still relatively low in many regions (with the exception of the Near East). Additional research in the coming years will be needed to clarify this important issue.

Archaeobotany of Early Agriculture: Microbotanical Analysis

Linda Perry
The Foundation for Archaeobotanical Research in Microfossils, Fairfax, VA, USA
Department of Geography and Geoinformation Science, Center for Earth Observing and Research, George Mason University, Fairfax, VA, USA

Introduction

Archaeobotanical research is conducted to gain an understanding of the relationships between ancient human populations and their surrounding botanical biosphere. To reach this goal, archaeobotanical researchers recover plant remains from archaeobotanical contexts, identify the botanical taxa present in the samples, and interpret the data within the cultural framework of the peoples who used the plants for various purposes including food, construction, and crafts such as basketry. Microremains are also used as tools to understand human impact on the surrounding landscape. It is the aim of archaeobotanical research both to gain a complete understanding of ancient plant use and to obtain the most solid, reliable evidence possible.

Perhaps the most common area of research is plant use and economy, a broad field of study that includes basic subsistence categories such as diet and construction materials, as well as more specific topics such as medicines or fish poisons. Because plants were often important economically, their remains can also be used to study migration and trade among human populations as seeds and other propagules moved from hand to hand across the landscape.

Another important archaeobotanical research subject is environmental reconstruction, which typically involves the coring of sediments in wetlands and subsequent analysis of the botanical microremains within. These cores and other samples from living and activity areas can also help us understand human adaptation to the environment including the introduction of plants into a new area, as well as their tending, cultivation, and domestication.

Finally, but no less importantly, archaeobotanical remains can be used to understand ancient human cultural activities including ideology and religion. Examples include plants in symbolic contexts; in art, as incense; and as hallucinogens for spirit journeys.

There are two major categories of archaeobotanical remains that are studied: macroremains, or large fragments of plants or their tissues, and microremains, the subject of this discussion, which are much smaller in size and, therefore, typically require more specialized equipment for both extraction and identification. Most microbotanical remains are of such small size that they must be viewed using instruments that allow for both high magnification and resolution. These instruments include the compound light microscope and the scanning electron microscope. Microremains are also, however, more durable than macroremains in harsh environmental contexts as well as at great depths where the heavy, overlying sediments can crush fragile charred specimens. Thus, microremains can be studied by archaeobotanists working in contexts that did not allow for the preservation and recovery of macroremains.

Key Issues/Current Debates/Future Directions/Examples

Microbotanical analysis is the study of ancient fragments or structures of plant tissues that are not visible to the naked eye, with the aim of understanding interrelationships between human populations and the plant world.

The three most commonly studied categories of microbotanical remains are pollen, phytoliths, and starch grains. All three types of microremains form in the tissues of plants and, just like the larger-scale flowers or fruits, differ in morphology between different groups or even species of plants. They are deposited in archaeological contexts via various methods, and archaeobotanists are able to extract them from sediments or artifacts, concentrate the extracts, and examine the assemblages of microfossils via microscopy. Microfossils can often be identified as being derived from specific plant taxa, and, thus, they are important indicators of plant presence and/or use in an archaeological context.

There are many similarities between the types of microfossils and how they are used by archaeobotanists, but there are also some key differences. This entry presents basic summaries of the three types of microfossils and how their analysis is carried out and then used as an interpretive tool in archaeobotany.

Pollen grains (Fig. 1) are microsporangiate reproductive structures that form in the anthers of flowers. If pollen grains are recovered from archaeological contexts, they can be used as markers to identify the remains of plants in archaeobotanical samples.

The extraction of pollen grains from archaeobotanical samples can also recover other microfossils that are made of very durable materials (Traverse 1988). The exine, or outer envelope of a pollen grain or spore, contains the material sporopollenin, and structures made by protozoa, fungi, or algae can consist of chitin, tectin, or other similar substances (Traverse 1988). These substances are resistant to degradation by the acids that are used by archaeobotanists to extract the microfossils from sediment samples, and, when considered as a group, these types of

Archaeobotany of Early Agriculture: Microbotanical Analysis, Fig. 1 A pollen grain from *Pinus* sp. showing the distinctive bisaccate form. Archaeologists sample for ancient pollen using methods that eliminate the possibility of contamination from modern pollen rain. This pollen grain was extracted from a starch sample. The *scale bar* is 20 μm in length

microscopic structures that occur in an assemblage are called palynomorphs (Traverse 1988).

The study of palynomorphs is called *palynology*. Archaeologists typically use palynology to provide evidence for three main purposes: environmental reconstruction, understanding human environmental impact, and documentation of the economic use of plants.

Environmental reconstruction involves the documentation of the species and diversity of plants that occur or move in and out of a system over time. Knowledge of the specific environmental requirements of each type of plant, such as rainfall, temperature, or soil conditions, then allows for an understanding of changes and/or stability in the studied environment.

The impact of human activities on the immediate environment is typically documented using specific changes in the plant community as well as other markers that may appear in the samples. Loss of timber species and the appearance of weedy taxa, for example, are good indicators that humans are clearing forest, perhaps for agricultural activities. If the landscape is altered, samples can show an increase in sedimentation rates as soil is exposed, and charcoal fragments indicative of burning activities may also occur.

The economic use of plants can be documented using pollen that may occur in specific contexts. Burials, for example, may include the ritual use of flowers that can then be identified. Identification will lead to a seasonal date of the burial due to the restricted time period in which the flowers bloom each year. Pollen can also be extracted from human coprolites. Typically, if the recovered pollen is from an insect-pollinated plant and is quite abundant, it can be interpreted as ingested. In contrast, pollen from wind-pollinated plants could have entered the system as "rain."

Pollen is identified using a one-on-one comparison with modern palynomorphs, and micromorphological features like shape and size as well as surface details such as pores and decorations are taken into consideration (Traverse 1988). Diagnostic forms occur in many plant groups but not in others (Traverse 1988). A three-dimensional viewing of pollen grains is usually required for identification, and taxonomic identification may be to the family, tribe, genus, or species level depending upon many factors including the types of pollen recovered and the quality of preservation.

When analyzing an assemblage of pollen remains, the archaeologist and paleoecologist must take several factors into consideration when making interpretations (Traverse 1988). First, the type of pollination system that the plant used is determined. Wind-pollinated plants make very large numbers of pollen grains that travel over distances. In contrast, insect-pollinated plants produce relatively few grains of pollen, and these grains will be dispersed only as far as the pollinator takes them. Some plants are pollinated by the movements of water, and these pollen grains tend to be very fragile and decay rapidly after deposition, while pollen grains from self-pollinated plants often germinate prior to the opening of the flower. Each type of pollination system will create a different signature, and, with the exception of wind-pollinated plants, most types of pollen are likely to be "underrepresented" in an assemblage or not represented at all.

Taphonomic processes can also affect a pollen assemblage. Degradation can occur due to the mechanical abrasion of sediment particles on pollen grains, the chemical destruction of the

structure by alkalinity, and biological activity of decomposers like fungi and bacteria can digest pollen grains.

Pollen samples can be collected in different ways that are dependent upon the questions the investigators wish to address. The main goals are to collect samples so that naturally occurring pollen rain can be distinguished from cultural deposits and to minimize modern pollen rain and cross-contamination within the samples.

Samples for pollen analysis, and for microbotanical studies in general, can include stratigraphic sequences, feature sediments, washes from artifacts, cores from lake beds or other sources, and control and/or comparative samples. Modern comparative collections are typically assembled from locally occurring flora. Pollen grains are stored on slides or in vials for the purposes of one-on-one comparisons with archaeological pollen grains.

Phytoliths (Fig. 2) are silica "bodies" that occur within and between plant cells. Plants produce phytoliths using soluble silica that is absorbed from the soil, and they are believed to occur in plant tissues for various reasons including the structural support of the plant, to aid as a detoxifying agent against damage from heavy metals that occur in soils, and for defense against small herbivores such as insects (Piperno 2006). Unlike pollen and starch grains, phytoliths consist of inorganic silica and, thus, are the most resistant to degradation in sediments. The relative stability of a phytolith in a sediment is dependent upon several factors including the comparative fragility of the phytolith in its native state, concentrations of various substances in sediments like iron and aluminum oxides that protect phytoliths, or extremely alkaline conditions that can degrade them (Piperno 2006).

Archaeobotany of Early Agriculture: Microbotanical Analysis, Fig. 2 A saddle phytolith (*center*) typical of those from grasses in the Chloridoideae. The presence of this type of phytolith in an assemblage is an indicator of the occurrence of chloridoid grasses in the sampled context. The scale bar is 20 μm in length

Phytoliths are extracted from sediments by chemical processing followed by a heavy liquid flotation (Piperno 2006). Notably, the processing techniques that are used to free phytoliths from sediment particles destroy pollen grains, and vice versa. Starch grains, in turn, are destroyed during the processing for both pollen and phytoliths. Thus, enough sediment must be collected from each relevant context if all analyses are to be employed. Phytoliths can also be brushed or washed from artifact surfaces. A sonic cleaner or sonic toothbrush can prove indispensable in extracting microfossils from artifacts, even in the field, and assemblages of phytoliths can reveal the function of the artifact in question.

As is the case with pollen, diagnostic phytoliths occur in some plant groups but not in others (Piperno 2006). Some plants produce commonly occurring or less-distinctive morphologies, while other plant groups do not make phytoliths at all. Two general approaches to the study of systematics within phytoliths are commonly employed within the discipline. The botanical approach studies phytoliths in situ, within the modern plant tissues themselves. The morphological approach studies disarticulated phytoliths that have been extracted from plant tissues. The goal of each approach is the same: to determine the typology for a particular plant or group of plants so that the remains can then be identified in the archaeological record.

To successfully identify phytoliths, a one-on-one comparison with modern specimens is used, and the microremains are viewed in three dimensions. The archaeobotanist must understand the local flora, both modern and at the time of interest, and must also have a grasp of which plants in the area may produce similar types of phytoliths. With this approach, the specific characteristics

necessary to separate groups can be determined, and secure identifications can be more reliably made. Like in palynology, the study of phytoliths is employed by archaeobotanists who are interested in studying environmental reconstruction, the impact of humans on their environment, and the economic uses of plants by ancient peoples.

Phytoliths are deposited in archaeological contexts via several mechanisms. Plant tissues can decay in situ, leaving behind the durable silica. Plants can also be burned, and phytoliths can bear the scars of fire with black markings or heat distortion. Digested plant materials, such as coprolites, will also contain intact, indigestible silica phytoliths. Via the careful analysis of context, archaeobotanists can collect phytolith samples from these cultural contexts and use them as tools to reconstruct ancient human activities. Phytoliths are also continuously deposited in non-anthropogenic contexts via the decomposition of plant tissues in "natural" systems.

As with pollen, sampling strategies for phytolith studies are typically dependent upon the research questions of the archaeobotanists. Cultural contexts, both sediments and artifacts, can be sampled, as can "natural" contexts like lake cores. Again, control samples can be key in determining the background "noise" and determining which deposits are culturally derived.

Starch grain (Fig. 3) analysis is the most recently applied method in the analysis of archaeobotanical microremains; however, due to the significance of starch in other fields including botany, food science, and industrial chemistry, it has been very broadly studied, and descriptions of both native and modified starches are common in various literatures (e.g., Reichert 1913 and BeMiller and Whistler 2009). Starch grains are the eventual product of photosynthesis in many plants, and they are formed in amyloplasts within the plant cell. Storage starches in particular are studied by archaeobotanists because they are both used for food and are diagnostic in morphology, while other transient starches that occur in plant tissues are not.

Archaeobotany of Early Agriculture: Microbotanical Analysis, Fig. 3 Starch grains from a modern comparative specimen of *Nothoscordum bivalve*, or "crow poison." Modern specimens are key in identification of ancient microfossils. The *scale bar* is 20 μm in length

Starch analysis has been used to document the origins of agriculture, the domestication of plants, and economic uses of plants. Because starches are much more likely to represent ancient foodstuffs than items such as construction materials and surrounding vegetation, studies of starch grains are typically, though not necessarily, diet focused. Just as is the case with pollen grains and phytoliths, diagnostic starch grains occur in many plant taxa but not in others.

Starch grains are identified very much like pollen grains and phytoliths are, via a one-on-one comparison with modern specimens and a three-dimensional examination of the morphological features of the grain. The archaeobotanist must have a grasp of the local plant communities, both modern and at the time of interest, and must also understand which related taxa in the area may produce similar types of starch grains. With this approach, the specific characteristics necessary to separate groups can be determined, and secure identifications can be more reliably made.

Starch grains can be deposited in archaeological contexts via various processes including the decay of discarded starchy plant tissues and through the processing of plant foods with, for example, cutting or grinding tools or cooking vessels. Thus, as with other microfossils, starch grains can occur both in sediments and on artifacts, and they can be extracted from both contexts. Extraction from sediments involves a chemical deflocculation followed by a heavy liquid flotation, while artifacts can be washed or treated with a sonic cleaner or toothbrush. Starch

analysis can be used in the study of dental calculus (Henry et al. 2011), and starch grains have also been extracted from human coprolites (Vinton et al. 2009). Both of these contexts document the actual ingestion of plant food resources.

The processing of starchy foods in laboratory settings allows archaeobotanists to compare damaged starches to those found in archaeological contexts (e.g., Perry and Quigg 2011). Both mechanical processing and heating, as would be applied in cooking, have been studied and documented archaeologically. These analyses allow for a more detailed understanding of the uses of ancient starchy food plants and a more comprehensive interpretation of ancient food-related activities.

Sampling for starch grains in the field, like in palynology and phytolith analysis, is dependent upon the research questions. Stepwise sampling of artifacts in the laboratory can include a dry brushing of the tool, followed by a wet brushing and a final sonic cleaning. This stepwise analysis can solidify the interpretation that the starch grains are directly associated with the artifact's function (Piperno et al. 2000), although, thus far, there has been no evidence that artifacts can be contaminated by decaying plant tissues in surrounding sediments.

Studies

Pollen studies, combined with phytoliths and particulate charcoal, have documented the sequence of farming practices in the tropical forests of Panama (Piperno et al. 1990) and helped document ancient cultivation of bananas in New Guinea at Kuk Swamp (Denham et al. 2003). Starch grain research has revealed the ancient use of millets in North China (Yang et al. 2012), ancient root crop agriculture in Panama (Piperno et al. 2000), the use of chili peppers throughout the tropics of the Americas (Perry et al. 2007), and the domestication of maize in the Balsas region of Mexico (Piperno et al. 2009). Multiproxy analyses using combinations of microremains are becoming more common. As an example, the integration of both phytoliths and starch grains revealed the early use of maize in highland Peru (Perry et al. 2006).

These are but a few examples of the many studies using microremains as tools for increasing our understanding of ancient agriculture throughout the world. These studies make a larger suite of economically significant ancient plants visible than can be recovered using macrobotanical analysis alone. As more archaeobotanists embrace these methods, ancient relationships between people and plants will be better understood.

Archaeological Archives

Jolene L. U. Smith
Virginia Department of Historic Resources, Richmond, VA, USA

Introduction

Archaeologists seek to reconstruct the past through the material record. In doing so, they produce a body of data of their own – the archaeological archive. Without these associated materials that document the fine details of an excavation, the artifacts themselves, however impressive, run the risk of losing much of their intrinsic value as tools for understanding past human experience.

Definition

Archaeologists document an excavation thoroughly, beginning well before the ground is broken with background research and development of a research design. During fieldwork, excavators create detailed maps and drawings, take photographs, and make extensive and detailed field notes. Once the excavation is complete, artifacts and specimens may be conserved and analyzed and the archaeological site interpreted in the form of a final report, scholarly work, or publication. Together, these supporting components make up archaeological archives.

Key Issues/Current Debates/Future Directions/Examples

Archaeology is by its very nature an act of destruction. As cultural features and artifacts are removed from their original physical contexts, embodied information risks being lost without careful attention to documentation at each step of the way. Maintaining this documentation is an ethical obligation for archaeologists and institutions that house archaeological collections and records. Stewardship of archaeological records is a component of the statements of ethics for the Society for American Archaeology, the Society for Historical Archaeology, and other professional organizations (Society for American Archaeology 1996; Society for Historical Archaeology 2003).

Archaeological record curation facilities are as varying as the sites themselves. Some record repositories are unique to one site or area. Others are affiliated with universities or cultural institutions, and yet more are divisions of government agencies. In some instances, collections of artifacts are stored alongside related documentation, and in others, different types of archaeological materials and records are housed in separate facilities determined by medium. Many artifact curation facilities have collection policies that specifically spell out requirements for non-artifact records associated with an archaeological collection in order to ensure that they are housed in a safe manner and that they may be useful tools for future research (Parks Canada 2009).

Good archaeological supporting documentation begins in the field. It is imperative that field notes are written legibly and all paperwork

properly labeled and organized before being sent off to a permanent repository for curation. The variety of media present within archaeological records can create a challenge for long-term preservation and storage. Large-format maps and field drawings, delicate photographs, scribbled and dirty field notes, computerized artifact catalogs, and other materials each require different accommodations and handling to ensure their survival over the decades and centuries. Environmental factors such as temperature, humidity, vulnerability to insects and other pest, and threats of damage by flood, fire, or intentional human effects like theft and destruction must all be considered when developing strategies and policies for managing collections of archaeological records.

The loss of provenience data is another major risk for archaeological archives (as well as recovered artifacts and specimens). Great care should be taken to clearly mark each document with appropriate reference numbers and dates in case individual pieces of documentation become separated from a larger collection. An important photograph of an archaeological feature or excavation unit may appear unremarkable and indistinguishable from any other when viewed out of context. Field records written on or with archivally unstable materials (Kraft paper bags, napkins, water-soluble ink, etc.) may be photocopied onto acid-free archival paper to ensure long-term survival. Photographs should be printed to archival standards in order to ensure that the chemistry is stable over time.

Many record curation facilities employ the use of relational databases to serve as an index to these diverse materials, often organized by site and/or provenance. This level of organization is key to maintaining the usability of all the collected information. A fundamental value of archaeological archives lies in their ability to make existing collections valuable tools for current research. When supporting documents become lost or damaged, the research value of the collection as a whole is greatly diminished. In order for archaeological collections to be a vital source of data for scholarly research, the associated records must be diligently maintained. A well-documented excavation and collection can produce data repeatedly, data that can be analyzed in a myriad of ways beyond what may have been envisioned by the original researcher without any additional destruction to the archaeological site (Nelson and Shears 1996).

The digitization of archaeological archives has had a major impact on data from a global perspective. As more and more countries move into the digital era, it is becoming possible to easily relate data between sites located across the globe. With an eye on interoperability of archaeological records and databases, researchers have developed projects like the Archaeological Records of Europe – Networked Access (ADS 2012), the Digital Archaeological Record (Digital Antiquity 2012), and the Digital Archaeological Archive of Comparative Slavery (Thomas Jefferson Foundation 2012). Although standards for data collection may vary from site to site depending on the excavator, government requirements, site type, and other factors, modern relational databases allow for information to be parsed in a way that enables broader inter-site analysis.

The nature of archaeological archives has changed at an astonishing rate over past decades with the increased ubiquity of digital data for information capture and storage. Instead of 35-mm film, many archaeologists only take digital photographs. Site mapping may be done entirely in Geographic Information System (GIS) or Computer-Aided Design (CAD) software, using GPS coordinates obtained from sophisticated units in the field (or even mobile phones). Artifact catalogs may be part of large databases, and final reports may exist in the form of interactive websites or as a single digital file. While these technologies introduce endless new opportunities for ways to process and disseminate archaeological data, they also prove to be a challenge for managers of archaeological archives. Technology is not always sustainable. If a digital record is created using a technology that becomes obsolete, the data may be lost forever.

Sophisticated analytical methods such as geospatial modeling and 3-D scanning may produce large volumes of digital data. Many contemporary facilities holding digital materials as part of archaeological archives are currently struggling with ways to manage an ever-increasing volume

of bits and bytes while keeping the data accessible. A disorganized box of paper site records is just as difficult to use as digital data that is not well maintained and indexed. Without a way to connect the information to the excavation and artifacts, knowledge is lost.

Because of the fragile and irreplaceable nature of many archaeological sites, access to information held as part of archaeological archives is often restricted to professional archaeologists and other approved researchers. In the United States, the Archaeological Resources Protection Act of 1979 allows government agencies to withhold any information from public access that may make the site vulnerable to looting or destruction. Great care should be taken to protect the physical location of archaeological sites while still allowing for an open flow of information.

Archaeological Chemistry: Definition

E. Christian Wells
Department of Anthropology, University of South Florida, Tampa, FL, USA

Brief Definition of the Topic

Archaeological chemistry, a subfield of archaeometry, is the application of techniques and approaches from chemistry and the chemical sciences to the analysis of the material record of past societies. Research in this field of study examines a wide range of human behaviors and formation processes including dating, provenance, technology, organic and inorganic residues, diet, migration, and human-environment interactions, among other topics. Early approaches are reviewed by Caley (1948, 1951, 1967) and more recently by Pollard and Heron (2008), who describe the most common applications today: obsidian characterization, clay and ceramic provenance, chemistry of archaeological glass and metals, composition of resinous substances, amino acid stereochemistry, lead isotope geochemistry, human bone (diet, nutrition, health, mobility), and biomolecules (e.g., DNA, dairy products). A number of important textbooks have emerged recently, including those by Pollard et al. (2007) and by Price and Burton (2012). These and related works, including a series of eight volumes from the American Chemical Society (from 1974 to 2013), emphasize the use of physicochemical instrumentation in solving archaeological problems, including (but not limited to) optical emission spectroscopy, atomic

absorption spectrometry, inductively coupled plasma emission spectrometry, mass spectroscopy, X-ray fluorescence spectrometry, analytical electron microscopy, proton-induced X-ray emission spectroscopy, neutron activation analysis, infrared and Raman spectroscopy, and various chromatographic techniques.

Archaeological Fieldwork

Robert Muckle
Department of Anthropology, Capilano University, North Vancouver, BC, Canada

Introduction

Archaeologists are guided in their fieldwork through a variety of instruments that collectively may be called codes of ethics. Such instruments are variously known as codes, principles, standards, statements, and guidelines.

These codes of ethics are often comprehensive, establishing guidance in all matters pertaining to archaeology, including but not restricted to fieldwork.

Many associations of archaeologists have such instruments, including the World Archaeology Congress, the European Association of Archaeologists, the Chartered Institute of Field Archaeologists, the Register of Professional Archaeologists, the Society for American Archaeology, and the Canadian Archaeological Association. Many other associations at national, regional, and local levels also have codes of ethics, as do subdisciplines of archaeology, such as the Society for Historical Archaeology.

Definition

All matters of archaeological fieldwork have ethical implications. This includes determining whether archaeological fieldwork should be undertaken, the methods of fieldwork employed, who should be able to do fieldwork, and how members of fieldwork projects should behave in both social and professional contexts at field locations.

In most situations, governments regulate the parameters in which archaeological fieldwork may be done, but it is codes of ethics that guide archaeologists working within those parameters, of how archaeology should be done.

Key Issues/Current Debates/Future Directions/Examples

Key issues and debates about ethics in archaeological fieldwork revolve around professional responsibility, archaeological privilege, and the culture of fieldwork.

It is a basic archaeological ethic to do good fieldwork, which is often embedded in the mindset of archaeologists through education and experience and codified in statements by archaeological associations. Codes of ethics are generally silent or vague on precisely what constitutes good fieldwork although it may generally be considered to include having a good research design, keeping accurate records, using appropriate methods, and, after excavations, leaving the site as close to its pre-excavation state as possible.

Although the precise meaning of doing good fieldwork is broad and vague, there are some emerging trends. This includes using noninvasive or nondestructive field methods where feasible. Rather than excavating, for example, this may mean using remote sensing techniques to collect data on subsurface deposits. Another trend which some see as an ethic related to good fieldwork is to do more of what may be called sustainable archaeology, reducing the ecological footprint of archaeological field projects. This includes more digital recording.

Archaeological fieldwork associated with human skeletal remains is a topic of considerable ethical concern and debate. Some archaeologists view the excavation and analysis of human skeletal remains for science as trumping the concerns of others, including those with cultural and/or biological affiliation to those being excavated. Many archaeologists, however, believe that the potential contributions to science do not outweigh the wishes of peoples with affiliations to the skeletal remains.

The ethics of working with the skeletal remains of Indigenous peoples has become an important part of the relationship between archaeologists and Indigenous communities in recent decades. As outlined by Allen and Phillips (2010), the World Archaeology Congress has been instrumental in advancing the rights and concerns of Indigenous peoples. Indigenous peoples generally prefer that ancestral remains are not excavated or otherwise disturbed, and when they are, then the remains should be turned over or repatriated to the group for reburial or another form of disposition such as cremation. Some codes of ethics explicitly prioritize the wishes of Indigenous groups in archaeological fieldwork.

Another issue concerns whether it is appropriate to do fieldwork at all. Fieldwork has long been a key component of archaeology, with archaeologists often preferring to collect their own data, whether searching for sites or excavating them. Doing fieldwork is often considered a rite of passage in archaeology, and designing and implementing a field project is often desired at the graduate level of studies for those pursuing advanced degrees to pursue archaeology as a career. This need or desire to do fieldwork is now being questioned by some archaeologists, especially those excavations undertaken for pure research or academic purposes, who believe that in many cases it would be more prudent to use existing collections of materials rather than undertaken new excavations and by so doing destroy part of the archaeological record.

Some archaeologists also suggest that recording previously undocumented sites and excavating sites in advance of development projects serves the interests of developers and government

rather than Indigenous peoples. In effect this practice may be seen to legitimize the destruction of the archaeological record, which is at odds with the ethic of stewardship. Hutchings and La Salle (2017: 72, 73), for example, suggest that CRM archaeology "has been largely ineffective at protecting heritage sites" and that "CRM can be seen as facilitating development by clearing heritage from the landscape."

Archaeological privilege is an issue that receives considerable debate, mostly concerning who are the rightful stewards of archaeological record. This includes such things as who controls access to field locations and issues permits to conduct archaeological excavations. A common theme in codes of ethics is that archaeologists should be stewards of the past, meaning that they should work toward preserving and protecting the archaeological record. This becomes an issue when other stakeholders in the archaeological record, such as Indigenous peoples whose ancestors created the archaeological record, view themselves as the stewards of their own heritage. In some regions of North America, for example, it is common for Indigenous groups to have their own permitting system, meaning in addition to receiving permits for fieldwork from government, archaeologists may be in a dilemma when Indigenous groups will not issue a permit or give permission in other ways. Doing fieldwork in some areas where there are overlapping claims of traditional territory may mean that archaeologists are faced with prioritizing the wishes of one Indigenous group over another.

Gaining permission from Indigenous groups to undertake fieldwork in their territory may be particularly difficult when archaeologists wish to do fieldwork on behalf of developers and governments to which the Indigenous group is opposed.

This dilemma is created, in part, by some codes that include responsibilities to both Indigenous groups and funding agencies without establishing priority.

Many codes of ethics indicate that fieldwork should only be undertaken by qualified archaeologists, with proper levels of training, education, and resources. Where this ethic becomes most contentious is when it comes to subsistence looting, defined by Hollowell (2006: 72) as "where people dig to find archaeological goods to sell and use the proceeds to support a subsistence lifestyle." Subsistence looting often occurs when traditional subsistence and economic systems have been irreparably harmed by natural or cultural forces, including conflict and invasions. This kind of subsistence looting has been widespread in the early twenty-first century in Afghanistan, Iraq, and Syria, for example, where local people subjected to years of conflict have looted archaeological sites in order to survive. It is not restricted to these areas or circumstances, however, with notable occurrences of subsistence looting being common in other regions and, in some cases, as part of the regular economic practices of local people.

While some archaeologists see all forms of looting, including subsistence looting, as wrong, others think subsistence looting is an exception. Those who see subsistence looting as wrong tend to privilege archaeology, following notions that archaeologists are the stewards of the past and that only qualified people should undertake fieldwork. Those who do not agree tend to privilege people over things, recognizing that when other subsistence and economic systems fail, many people are left with little choice but to loot sites. Some archaeologists also think looting of sites by local Indigenous people with cultural and biological affiliations to the sites being looted is acceptable. In this case, they may be following an ethic prioritizing Indigenous peoples' rights to their own heritage.

Archaeologists also may find themselves in an ethical dilemma when working with treasure hunters. Beaudry (2009), for example, notes dilemmas may occur when archaeologists are hired to work with commercial treasure hunters. Some associations deem such work unethical. For many, working with commercial treasure hunters goes against an ethic of not becoming involved in the commercialization of artifacts.

Providing safe working environments is another common ethic in field archaeology. Archaeologists are tasked with providing safe work environments and taking appropriate

measures to reduce risk, including a wide range of situations ranging from using appropriate stabilizing equipment or shoring of walls during excavation to reducing the danger of encounters with wild animals. Providing a safe working environment also includes providing an environment free from harassment and abuse. Despite this basic ethic, sexual harassment and abuse in field locations have been well-documented in recent years (e.g., Clancy et al. 2014; Meyers et al. 2015), and some associations are modifying their codes to address this.

Statements of ethical concerns, whether framed as codes, statements, principles, or guidelines, are now common among archaeological associations. They can usually be found on the websites of the associations.

Archaeological Informatics

Stuart Jeffrey
Archaeology Data Service, University of York, York, North Yorkshire, UK

Brief Definition of the Topic

Archaeological Informatics is the practice of analyzing, managing, and preserving archaeological information. This can include information relating to tangible and intangible heritage, and the term generally adheres to both information and data, created or held in digital formats. Such data might be held in databases, geographical information systems, as digital documents (such as text, spreadsheets, images, audio, video), as well as more complex digital objects such as CAD, remote sensing formats, and 3D datasets. It also refers to both the dissemination and the collection of information via digital media, such as the World Wide Web.

Just as digital technology has had an incalculable impact on multiple spheres of human

experience, Archaeological Informatics has revolutionized archaeological practice in a number of ways, most noticeably in the near universal use of databases to store, manipulate, analyze, and ultimately disseminate archaeological information. It has also challenged traditional models of paper-based archaeological publication, particularly through broadening access to underlying datasets and to other traditionally unpublished material, such as gray literature, via the Internet. It is also true that Archaeological Informatics does not fundamentally remedy issues of representation, partiality, categorization, and interpretation that are inherent in the data themselves irrespective of the media in which they are held. The potency of digital media itself, particularly in terms of its association with modernity, precision, accuracy, and scientific approaches, may even add additional complexity to the task of critically assessing data for interpretative purposes. This is especially true where data are being consumed by nonexpert audiences where, for example, data presented as a three-dimensional model might appear inherently more trustworthy than the same data presented as a hand-drawn image.

Breaking down barriers between isolated archaeological datasets remains a constant challenge in Archaeological Informatics because the adoption of archaeological information systems and digital recording techniques has generally taken place in advance of formats and systems that allow sharing of the data out with the project or organization in which it was created. Recent developments have begun with regard to data standards, that is, shared categories, definitions, and data schema, which facilitate meaningful comparison between cultural heritage records and the aggregation of these records nationally and internationally. This will have a significant impact on both how the heritage is curated and how it is presented to the public. The most obvious benefit to curation has been that digital sources, such as national and local monument inventories and digital repositories containing significant resources, need no longer be hermetic entities relating to a specific geographical period or subject boundaries but can make their content available as part of a larger aggregated dataset. Thus, researchers and cultural heritage managers are much more likely to be able to retrieve data on their area of interest from a single point of access without being constrained by arbitrary, technical, political, or regional boundaries.

Two important points which arise with regard to data standards are, firstly, they should be reactive to how data is gathered rather than proscriptive and the role of arbitrary classification should be balanced against the creative process of interpretation. Secondly, the level of their adoption is far from universal even in countries where such standards exist, recasting legacy datasets as compliant to data standards can be time-consuming and costly even using data-mining and natural language processing techniques. As well as local or national standards, the CIDOC Conceptual Reference Model provides an international standard with definitions and formal structures for describing the implicit and explicit concepts and relationships used in cultural heritage documentation. A number of countries also have national and or regional policies explicitly intended to create cultural heritage data infrastructures and/or aggregation services for cultural heritage resources or participate in projects with this aim, such as the NSF "Cyberinfrastructure" program in the USA, the EU-funded Europeana project, and the multi-European-government-funded Digital Research Infrastructure for the Arts and Humanities (DARIAH).

At the same time as standards development extends the interconnectedness and utility of archaeological datasets, a broader shift in Internet technology toward the "Semantic Web" has prompted a change in the publication of datasets online to linked data format (i.e., expressed as a series of dereferencable URIs linked together in subject-predicate-object triples). This acts to extend the linkages between archaeological and cultural heritage datasets to any other appropriate dataset, or data point expressed as linked data. In some countries, the driver for the adoption of this approach to structuring data is being explicitly driven by government policy (e.g., the UK data.gov.uk program). The impact that this change will

have over time in widening access to cultural heritage information and embedding it in a broader "semantic Web" could potentially be on a scale of significance similar to that of the original World Wide Web.

A further significant focus for Archaeological Informatics is the representation of uncertainty. This is still considered a challenge more generally in informatics, but has particular implications for systems holding cultural heritage information. Many aspects of cultural heritage defy precise definition, geographically, temporally, and culturally, and even where the subject matter is amenable to some form of precise definition, there is often a lack of certainty due to incomplete evidence or competing interpretations. For example, for in-building or development control purposes, precise boundaries for archaeology may be desirable, but some indication or representation of the "fuzzy" or contested nature of the data from which the boundary is derived is necessary to make the boundary actually meaningful when making decisions.

Perhaps the most significant issue facing archaeological informatics is the growing realization that digital data is extremely prone to corruption, loss, and software and hardware obsolescence. This is a particularly important point as virtually all archaeological data, from primary data to synthetic analysis, is now "born-digital," that is, it is originally created in digital form whether that be a simple word processing document or a three-dimensional laser scan. Much of this data, if lost, cannot be recreated. The need for all sectors of archaeology to have access to reliable and (preferably publically) accessible repositories with expertise in digital preservation and cultural heritage content remains a key concern in Archaeological Informatics. There are still few organizations able to offer viable preservation and access services specifically focused on the cultural heritage domain although good examples are the Archaeology Data Service in the UK (ADS), Data Archiving and Networked Services (DANS) in the Netherlands, and Digital Antiquity's data archive (tDAR) in the USA.

In tandem with the challenges relating to digital preservation, there has been a rapid expansion of opportunities for public dissemination and engagement provided by new media, particularly Web-based technologies such as social networking, public participatory GIS, (PPGIS), and other forms of user-generated content. These have to a certain extent blurred traditional boundaries between "expert" and "mediated" material and content, including interpretation, memories, opinions, and records of the cultural heritage generated by the broader community. This process can raise challenges for cultural heritage managers, such as understanding conflicting or contradictory viewpoints, as well as significant opportunities such as expanding the knowledge base and tapping into the many alternative perceptions of what actually constitutes the heritage.

Archaeological Institute of America (AIA)

Andrew M. T. Moore
Rochester Institute of Technology, Rochester, NY, USA

Basic Information

The Archaeological Institute of America (AIA), located at 44 Beacon Street, Boston, Massachusetts, 02108 USA, http://www.archaeological.org, is the oldest learned society in North America devoted to archaeology. It is also the largest with over 200,000 members. The AIA was founded in Boston in 1879 under the leadership of Charles Eliot Norton of Harvard University (Sheftel 1979: 3). It has a unique structure based on local societies, now numbering over 100 across the United States, Canada, and overseas. The AIA counts among its members professional archaeologists, most of whom work in the Old World, and members of the general public with a deep interest in archaeology. The coexistence of these two groups has shaped the AIA throughout its history and continues to be a fundamental element of its character.

The AIA promotes archaeological research and disseminates its findings, notably in a scholarly journal, the American Journal of Archaeology; in a popular magazine, Archaeology; and in professional monographs. Endowments enable the AIA to fund grants for field surveys, excavations, and laboratory research. The Institute holds an annual meeting at which archaeologists present their latest results to colleagues and interested members. Through its local societies the AIA supports a nationwide program of public lectures and other programs designed to inform the wider public about archaeology and significant recent discoveries. It has also developed educational programs for children. In recent years the AIA has initiated a program to preserve prominent archaeological sites worldwide and to promote best practices in site conservation. News about archaeology and the activities of the Institute is communicated to members and the public through a newsletter and, increasingly, the worldwide web. The AIA provides a fellowship program for its younger academic members and also funds students who wish to gain some experience of fieldwork. Several awards recognize archaeologists and others who have made outstanding contributions to the field and to heritage preservation. The most significant of these is the Gold Medal for Distinguished Archaeological Achievement. This has been given to such distinguished archaeologists as George Bass, Robert Braidwood, Hetty Goldman, and Gordon Willey. Additional awards honor scientific contributions, books of special note, and excellence in undergraduate teaching.

The AIA has long campaigned to end the international traffic in antiquities, arguing that this destroys our shared heritage from the past. Recently, the Institute has spoken out against the large-scale destruction of archaeological and historic sites in the Middle East and elsewhere. It has joined with other organizations to support efforts to mitigate such damage.

In the beginning the members of the Institute were mostly Harvard faculty and leading figures in the Boston business and social communities. Within a decade of its founding the AIA could claim to be national in scope as local societies were founded in New York, Baltimore, and across the Midwest (Allen 2002: 12). Early in the twentieth century the number of societies grew still farther across the western states, including California. In 1906, the United States Congress approved a Charter for the AIA (Sheftel 1979: 14), an indication of the organization's growing national prominence. That document set out a mission for the Institute that continues to inspire its activities today. The Charter states that the AIA was founded

> . . . for the purpose of promoting archaeological studies by investigation and research in the United States and foreign countries by sending out expeditions . . ., by aiding the efforts of the independent explorers, by publication of archaeological papers, and reports of the results of the expeditions which the Institute may undertake or promote . . .

In its early years the AIA sponsored excavations at the Pecos Pueblos in New Mexico, at Assos in Turkey, in Crete, at Cyrene in Libya, and also in Guatemala, Mexico, and at Nippur in Iraq. The Institute considerably expanded its reach through the establishment of schools of archaeology around the Mediterranean and in the Southwestern United States (Sheftel 1979). Among the most prominent were the American School of Classical Studies at Athens, the American School of Classical Studies in Rome (now the American Academy in Rome – School of Classical Studies), the American School for Oriental Study and Research in Jerusalem (now the American Schools of Oriental Research), and the School of American Archaeology in Santa Fe, New Mexico (now the School for Advanced Research on the Human Experience). Later, schools of archaeology in Baghdad, Cairo, and Tehran were added to this list.

From the beginning the Institute developed a special interest in the archaeology of the ancient civilizations of Greece and Rome, together with the high cultures of the ancient Near East. This continues to be the focus of many of its professional members today and is reflected in the contents of theAmerican Journal of Archaeology. Thus, for some of its members, the archaeology of the lands surrounding the Mediterranean has been of primary importance (Renfrew 1980). Others associated with the Institute, however, have had more diverse interests within archaeology, extending widely across the Old World and into the New World as well. Indeed, this dichotomy has been part of the Institute's character from its founding as its early exploration of sites in the Southwestern United States demonstrates. Currently, that wider array of interests finds expression in the pages of the magazineArchaeologyand in the lecture program, both of which embrace the exploration of the entire human past across the globe. Through these means, and also in the site preservation program, another global initiative, the Institute has a global reach.

Major Impact

Today the Archaeological Institute of America can claim to be the leading organization devoted to international archaeology in North America. It continues to provide significant support for professional archaeologists and their research while expanding its outreach to members of the public, including children. The AIA has become a leader in the worldwide heritage preservation movement. Its role as an advocate for the safeguarding of the record of the human past has become one of its defining characteristics. The AIA's rich array of activities is captured concisely in its motto "Excavate, educate, advocate."

Archaeological Licenses

Thomas R. Wheaton
Querétaro, Mexico

Introduction

The licensing of archaeologists is one part of a system of quality control of archaeological heritage management (AHM), sometimes known as archaeological resource management (ARM), cultural resource management (CRM), contract archaeology, rescue archaeology, and preventive archaeology. The other two parts of quality control are: oversight of an ongoing project by the appropriate government agencies; and review and approval of the final product or report by the proper authorities. Licensing often involves requiring registration of qualified archaeologists at the national or provincial or even local level, and it can also involve review of a candidate's qualifications on a project-by-project basis. Such a review can include personal interviews and submission of prior work upon which to base a certification of the archaeologist's ability to complete a project in an acceptable manner.

Definition

While quality control in archaeology has always been an issue, it did not really come to the forefront of consideration until in the mid-twentieth century; archaeology moved out of the academy and government and into the private or contracting sector. Prior to that time, only archaeologists knew or cared enough about the quality of archaeology to make it an issue, and the quality of archaeologists and the work they did was thus generally controlled by peer pressure and academic ethics and organizations. As the public and non-archaeologists became more involved in archaeology through taxpayer and polluter-paid funding and by projects that were of more immediate local public concern, there arose a need for non-archaeologists to judge the qualifications of archaeologists, about which the average citizen, politician, and government bureaucrat knew virtually nothing.

Taxpayers and clients hiring archaeologists needed to know that their money was being spent in the most efficient and effective manner possible to protect the public's common archaeological heritage and to get approval and permits for development projects. The inherent conflict of interest involved in academic archaeologists or government agencies accrediting their own work also argues for the application of some kind of independent certification or licensing of such archaeologists so to protect the public's interests when public funding is involved. Despite this, however, licensing is generally only accepted by, and applied to, private-sector or contract archaeologists.

Qualifying archaeologists prior to commencement of a project, or in other words licensing, can be thought of as a "front-end" approach to quality control, and in some countries this is the full extent of attempts to control the quality of the work done. If you pick a well-qualified archaeologist, the thinking goes, the work done and the final product must be acceptable. This is a common system in countries with legal systems based on the Napoleonic code and in the Latin tradition.

Peer review of the final report of a project attempts to control quality by reviewing what the archaeologist has done to see if the completed work meets certain standards. This is usually accompanied by inspection of the project in progress and can be considered the "back-end" approach to quality control. This is a common system in countries based on Saxon or British common law.

Both the "front-end" and the "back-end" approaches have their advantages and disadvantages, and in most countries both approaches are used, with one or the other receiving most of the emphasis. Even in "back-end" countries like the United States, the United Kingdom, and Australia, where the government is not involved in prequalifying or certifying archaeologists beforehand, the qualifications of archaeologists are taken into consideration before awarding a contract. And conversely, in "front-end" countries

such as Namibia, Portugal, and Ireland, there is some review of the final product at the completion of the project. In countries, such as France and Mexico, where there is no licensing, since archaeology is a monopoly of the state, the final product is subjected to at least a cursory review, and it is assumed that the archaeologists hired by the state are qualified at some level. In some countries, for example, the Netherlands where there is a recently instituted private sector, AHM is controlled by a complete system of "front-end" licensing, in progress inspection, and "back-end" review. But such a complete system of quality control, if not unique, is unusual at the beginning of the twenty-first century.

Key Issues

What is considered adequate work depends on the country and the laws and customs where the work is conducted. Neither the "front-end" nor the "back-end" approach by itself is sufficient to ensure that the work conducted is adequate in any country. The major drawbacks for the "front-end" approach are that the work may be poorly executed and a final report never submitted, which has often been a major problem of academic archaeology. For the "back-end" approach, the work conducted may turn out to have been inadequate, but once an excavation is completed the site and data it contained have been destroyed, cannot be replicated, and are irretrievably lost. Clearly, both approaches accompanied by ongoing project review, as in the Netherlands, are necessary to assure that the public's money has been spent wisely and that the archaeological data has been collected to protect the public's common heritage.

It was mentioned above that even in "back-end" countries, where the government does not require a formally recognized register of qualified archaeologists, there are often informal qualifications standards, if for no other reason than that the client, such as a local government requiring national government review or a private developer needing an adequate level of investigation to obtain a building permit, must be assured that the work that will be done is sufficient to pass review prior to spending their money. In many of the "back-end" countries, NGOs have been instituted whose main purpose is to certify the qualifications of archaeologists and archaeological contracting companies. Two prime examples are the Register of Professional Archaeologists (RPA) in the United States and the Institute for Archaeologists (IFA) in the United Kingdom.

In the USA, there is no licensing at the federal, state, or local level, although federal agencies who oversee the implementation of the major AHM legislation suggest and sometimes require that archaeologists have a minimum level of education and experience. However, there is a private, nonprofit NGO, the Register of Professional Archaeologists (RPA), which certifies the educational and experiential qualifications of its members who join the organization voluntarily. RPA members who break the rules can be, and have been, expelled from the organization. Hiring an RPA member provides some assurance to the client that the work will be adequate and will pass review, but there is no requirement at any level of government in the USA that archaeologists be RPA certified, and few clients even know of the existence of the RPA. In the UK, the Institute for Archaeologists (IFA) has improved on the RPA by certifying not only individual archaeologists but archaeological contracting companies, including periodic inspections by the IFA of a company's financial and personnel records. The British government does not require that contractors be IFA certified, but clients hiring IFA-certified companies are assured that the individuals in the companies and the companies themselves are qualified. In addition, British clients are learning of the IFA and are increasingly requiring IFA certification of their contractors.

One of the major benefits of certifying companies rather than individual archaeologists is that companies, because of their varied work force, have expertise in various subspecialties that an individual archaeologist could not have, including such things as business management and meeting contract requirements, bio-archaeology, regional and temporal specialties, rock art, physical anthropology, and other specialties often necessary for the successful completion of a project. Even in countries that have no private sector, it is often the case that a government agency might have a

particular type of expert, but scheduling may prevent that expert from being available in a timely manner to complete a project. Thus, the private-sector contracting system is often more flexible and able to address a variety of situations than single-source, centralized, governmental agencies. If one company is not available, another qualified company usually is.

Perhaps the main reason for the development and thus licensing of a private sector is the lack of sufficient personnel in government agencies and academia. This is often for a lack of financial resources even in developed countries. As an example, in the United States the main AHM legislation was passed in 1966. Over the next few years, clients doing work for or requiring permits from the federal government began looking for archaeologists to meet the new requirements. There were few if any governmental archaeologists available to do the work so developers seeking archaeologists looked toward the universities. At first, the universities met the need by using student labor, often managed by university graduate students. This was inexpensive and provided experience to students, but the quality and timeliness of the work varied greatly. By the mid-1970s, the demand outstripped the ability of universities to respond appropriately and within limited time frames. Some universities tried to set up separate contracting arms within the university, but these were generally poorly managed, underfunded, and unable to meet schedules and budgets. As a result, the private sector was instituted, often with a graduate student or professor setting up a company on his/her own. By the early 1980s, there were so many of these extra-academic archaeologists and companies that developer clients could not determine if their contractors were qualified, since they were not clearly associated with a recognized university program. A need for some kind of certification was born, but, in the USA at least, it was not adequately met. The RPA which had been started in the early 1970s has never really caught on as a certification group by clients or government agencies, and as a result, the USA is still today without a system generally recognized by clients and government review agencies. Thus, the USA still has primarily a "back-end" system.

Examples

A perusal of the IFA, RPA, and the Dutch Archaeology Quality Standards gives a set of standards that could serve as a framework for certification in countries presently operating without such standards and who wish to develop a more well-rounded quality control system to meet the needs of their taxpaying publics, of developers requiring such work, and of their archaeological resources. Such standards might also be worth reviewing by those countries who already have a "front-end" system and even for those with a closed governmental monopoly.

Some of the major points in these standards state that a professional archaeologist should:

- Insure that any work conducted is replicable, management and results are open and transparent, and that methods are clearly stated and adequate to the job
- Provide for publishing the data in a timely manner and as completely as possible for use by other archaeologists and the public, and that the data is preserved for the future whether the work is paid for by the government or by the polluter-pays principal
- Abstain from dishonesty, fraud, and misrepresentation in dealings with others
- Deal fairly, responsibly, and ethically with colleagues, employees, and clients
- Cooperate with other archaeologists and the public and descendant groups
- Insure that the archaeologist has the necessary expertise to do a competent job
- Abide by laws protecting the resource and employees
- Protect client's privacy and interests if not in conflict with archaeological ethics
- Assure the timely completion of an adequate project
- Be aware of safety for employees and the public
- Avoid conflicts of interest
- Support and promote conservation of the resource base and the interests of descendant communities
- Not knowingly recover artifacts for commercial exploitation

- Give credit where credit is due
- Keep up with developments in the field
- Not commit plagiarism or falsely attack the reputation of another archaeologist
- Not take bribes
- Ensure that the research results will justify the destruction of the resource
- Avoid exaggerated and sensationalist statements about archaeological remains
- Be informed about the research at hand and before dealing with the public or giving legal testimony
- Report violations of the code of conduct to the proper authorities in a timely manner
- Insure that archaeologists and agencies put the archaeological resource first, and not their political agenda

Basic Information

In the same way that the development of medical technology has contributed to make surgical interventions less intrusive, by using images generated by X-rays, ultrasounds, and nuclear magnetic

resonances and complementing them with biopsies, clinical analyses, etc., so, in the last few years, archaeological prospection has made available a variety of images from the subsoil that contribute to optimizing excavation strategies and accurately defining the areas and depths at which one can recover the information that is relevant to the objectives of an archaeological project.

Unfortunately, exploratory studies prior to excavation are well behind and a long way from being a generalized archaeological practice, unlike medicine, where you would not conceive of carrying out any surgery without applying all of those tests. Nonetheless, the international trend is, more and more, to make use of the information provided by techniques that can give details about the conditions of the subsoil, and so reduce to a minimum any disturbance of the archaeological context caused by excavating, and at the same time recovering as much information as possible. This is where the activities of the Archaeological Prospection Laboratory come in, which, during the last 30 years, has developed procedures, technologies, and tools for the study of archaeological sites in Mesoamerica.

Background of the Laboratory

The Archaeological Prospection Laboratory was created in early 1983, with a proposal to incorporate, develop, and adapt instruments, techniques, and methods that permit to obtain data and interpret archaeological sites from the ground surface.

After training at the Lerici Foundation in Italy in 1981, Luis Barba outlined a plan to gradually incorporate various techniques into the laboratory, in the same coordinated way that the Italians have come to use so successfully. After further training at the University of Georgia getting his Masters Degree, Barba returned in 1983 to establish the laboratory. In that year, a mobile laboratory was designed and built to facilitate the acquisition of geophysical data and perform chemical analysis in the field. With this infrastructure, the laboratory began to take part in archaeological projects, with the purpose of carrying out exploration studies prior to any excavation work.

In 1985, Barba defended a Master's thesis at the University of Georgia that proposed a methodology for the surface study of archaeological sites that is still being applied by the laboratory. In this way, the Prospection Laboratory established a process that includes the application of remote sensing, geophysics, geochemistry, and archaeological techniques. This has been called the methodology for studying sites from the ground surface, and it provides information about the characteristics of the context and the buried structures, which permits decision-making about whether to excavate or not, and then where to excavate, based on scientific data.

In favorable conditions, it has been possible to obtain data about the function of a site before its excavation. This presents unquestionable advantages in the quantity and quality of the information that can be retrieved as well as the time and cost that the archaeological investigation will require.

The methodology mentioned incorporates a variety of archaeological exploratory techniques, organized in such a way that their application is as efficient as possible. Essentially, it makes use of a wide range of techniques such as satellite imagery and aerial photography to locate and delimit the sites. It records the conditions of the surface using the topography and the distribution of scattered material. The geophysical techniques are located at an intermediate level as regards the area of land that they cover, which shows the limits of the sites and the localization of the structures that form it.

At the last stage of this procedure, the samples taken from the site are chemically analyzed. In this way, at each stage of the process, the data obtained in the previous stage is detailed and verified. In every case, the variations detected for each indicator are represented by way of computer-generated maps and immediately after the acquisition of data to provide a constant feedback (Barba 1994).

In this way, it is possible to cover several hectares in a few weeks of work, but at the same time, the results offer a sufficient level of detail in the areas of interest to guide subsequent excavation work. Recently, the quality of

surface data has allowed us to visualize and understand complete archaeological sites without the need for any excavation.

Prospection Techniques

The laboratory has experimented with a variety of tools. One of the most successful has been the use of balloons to lift photographic cameras, triggered by remote control, to acquire aerial images for archaeology. That, complemented by the processing of images to produce digital mosaics of the site and combined with topographic surveys, has permitted a comprehensive recording of the surface using digital terrain models (DTM).

As one part of the technology used in archaeological exploration, geophysical techniques are utilized to identify what is below the surface and, by way of indirect observation, what materials have different physical properties. The most common techniques include measuring magnetic properties, currents and electric potentials, and the reflection of electromagnetic waves in the terrain that is being studied.

In archaeology, the techniques of geophysical prospection offer the advantage of being able to investigate areas in less time and with less cost than the use of traditional methods. As with other research techniques, they also have their limitations, as there always exists some uncertainty in the interpretation of the data. Generally, one has to decide between the penetration (depth of investigation), the required resolution, and the speed of accomplishing the fieldwork. It is very difficult to achieve rapid and inexpensive measurements that will reveal in detail the deep structures, by using only one technique; because of that, our work includes many of the currently available techniques, applied in a systematic and coordinated manner. Despite the undoubted contribution of geophysical techniques, our laboratory has never abandoned the use of chemical techniques, and the expected arrival of new elemental analytical techniques with portable XRF promises to revitalize the role of chemical techniques in archaeological prospection.

Major Impact

Main Contributions of the Laboratory to Archaeological Investigation

Throughout the 30 years of its operation, the laboratory has developed many analytical techniques and applied them in over 100 archaeological sites in which it has worked in various parts of the world. One of the most significant achievements is the establishment of the integrated methodology that has permitted, through the application of remote sensing, geophysical exploration techniques, and chemical techniques, enormous detail in the study of archaeological sites before initiating excavation. As is shown in Fig. 1, each technique collects data that are converted into images, producing layers of information, each time more accurate, of the archaeological site that is still buried.

As a consequence of applying chemistry to prospection, another significant contribution was made to the study of occupation surfaces: it was in this laboratory that, at the end of the 1970s, a research project was designed to reconstruct human activities by analyzing the chemical residues on floors of the excavated sites. In the early 1980s, the laboratory gradually incorporated geophysical tools in its fieldwork, at the same time reducing the role of chemistry in prospection but promoting the study of chemical residues, first on floors of occupied houses (Barba and Bello 1978), later on floors of archaeological houses, and finally on ceramic vessels.

The chemical study of floors has provided evidence of the activities carried out on them, allowing us to understand the use to which the spaces were destined. Such is the case in the identification of areas for food preparation, consumption of food, ritual zones, transit zones, storage, etc. Recently, the efforts of several laboratories have made ICP, XRF, GC-MS, and other analytical techniques available to detect those residues on floors (Middleton et al. 2010).

It has been also incorporated the study of residues impregnated in the pores of ceramic vessels in order to infer what liquid substances they once

Archaeological Prospection Laboratory (National Autonomous University of Mexico), Fig. 1 Diagram showing the application sequence of analytical techniques used in the Archaeological Prospection Laboratory. (After Barba 1994)

contained. The analyses applied as much to the floors as to the ceramic vessels include tests for phosphates, carbonates, pH, protein residues, fatty acids, carbohydrates, and sometimes the determination of color (Barba 2007). On occasion, additional tests to detect iron, nitrates, chlorides, and calcium have been applied to resolve specific problems. Nowadays, XRF has been incorporated to also identify some elements with cultural importance.

Archaeological Record

Michael J. Shott
Department of Anthropology, University of Akron, Akron, OH, USA

Introduction

Read history if you wish to learn the past? Well, yes and no. Read history, by all means. But the human past – hundreds of thousands to millions of years – vastly exceeds the 5000 years of written records which, in any event, are highly uneven in time-space coverage even during that comparatively brief span. For most of the human past in most corners of the world, the archaeological record is our sole or chief source of evidence. The historical record is texts of various kinds. But what exactly is the archaeological record?

Definition

Everyone knows, or at least think they do, that the archaeological record consists of the material remains left behind by past societies. In the narrowest sense, this much certainly is true. An ancient hunter discarding a butchered animal bone, an ancient cook discarding the broken shards of a pot, and an ancient despot raising a monument to his or her glory that, like the statue of Ozymandias, at length falls to abandonment and disrepair all contributed to the archaeological record. The record, therefore, consists of all things that ancient people made, used, or otherwise transformed from their natural state and place. It is indeed material things that range in size and makeup from old bones and stones, dusty bricks, and shards of pottery vessels to palaces and pyramids. But archaeologists and even students in their introductory classes know that the record is not just material things but also abstract or intangible *context*. It is not just the old bones, broken shards, etc., but where they are found, associated with what else, and in what depositional matrix. The archaeological record is old things and contextual information about them.

Artifacts and other material things in the record possess intrinsic properties like their composition, size, and form, which characterize them whatever the nature of the record. Extrinsic properties include objects' abundance or number, their distribution, and their patterns of association. Extrinsic properties of things in turn comprise intrinsic properties of the archaeological record. The theory that explains how the record formed says nothing directly about objects' intrinsic properties but a great deal about their extrinsic ones, in the sense of what and how much is deposited, where, and with what.

Whatever its nature, the archaeological record is not entirely a thing of the past. It may have

originated in "Thens" beyond number, but it is accessed in painfully finite "Nows." Archaeologists often emphasize the record's status as a contemporaneous thing to distinguish what we do from ethnography, the study of contemporaneous cultures by direct observation, not indirect inference from material remains in context. But the record is contemporaneous in another sense because "Nows" of different times involve different methods by which to recover the record. Fifty years ago, for instance, tiny and nearly invisible fragments of plants and animals that ancient people ate were overlooked in archaeological deposits, too small to detect and systematically to collect. With the development of flotation methods, representative samples of those abundant and important parts of the record became commonplace, in the process altering our understanding of the past. Physical science methods allow us to identify trace elements in archaeological materials from pottery to stone and beyond in ways that earlier generations of archaeologists could not imagine. What parts of the archaeological record are accessible, and how, are themselves historical artifacts. Whatever he had in mind, so far as it concerned the archaeological record, Faulkner was righter than he knew in saying "The past is. . .not even past."

Historical Background

For most of archaeology's own past, however, there was precious little self-conscious reflection about what the archaeological record was. It was there, and it clearly was meant to be dug and documented. Archaeologists simply got on with the task.

At a particularly influential moment in its history, though, a prominent American archaeologist argued that the material record and context "present a systematic and understandable picture of the total extinct cultural system" (Binford 1962: 220; original emphasis). Salutary against the then-prevailing belief that the record revealed comparatively little about the past (e.g., Hawkes 1954), this optimistic view excited enthusiasm for ambitious attempts not just to learn the chronological order of things or to engage in sterile exercises in object classification but to determine how the record registered, if obliquely, the structure and organization of the past cultures that left it behind. Initial enthusiasm may have overreached, less so than some believe today, but had the virtue of rescuing archaeology from its traditional preoccupations with time order and taxonomy. In the process, archaeologists were prompted not only to think about what the record revealed of the past but also to appreciate that learning how the record formed was essential to revealing that meaning.

Besides its promise, this appreciation naturally led archaeologists to contemplate limitations of the record. Obviously, limitations include the natural processes like organic decomposition that reduce or alter the record after its deposition and those like disturbance by animals – "bioturbation" – that alter its context. Perhaps less obviously until archaeologists began to think about it, another limitation is that the record as deposited is neither time capsule nor preserved Pompeii. Instead, it is a confusing scramble of things used in different ways at different times for different purposes, all thrown together at the point of abandonment or discard with (as it seems to some of us at weaker moments) no regard whatsoever for the inferential challenges confronting future archaeologists. (Schiffer (1976) termed these "natural-" and "cultural formation processes," respectively.) Confusing this scramble of things may be, but arbitrary it is not. Yet until the systematic properties of the scrambling process are, well, unscrambled, archaeologists cannot understand the record or, by extension, the past that it reveals. Failing to understand the complex, secondary patterns of association that dominate the archaeological record, for instance, anyone troubling to examine a family's trash when it contains food scraps, rosary beads, broken tools, and fragments of shingles might mistakenly conclude that it dined on the roof using screwdrivers while adorned in curious jewelry.

Thus arose formation theory which, broadly speaking explains how the record formed and why it formed as it did (Schiffer 1976, 1987; Binford 1981; Shott 2006). It is one thing to know that how the record formed is critical to its

grounded interpretation. It is quite another thing to accomplish this task in practice. Doing so requires knowing the record both for its promise and the limitations only briefly noted above. If, as David Clarke (1973: 17) once said, the archaeological record was "indirect traces in bad samples" of what ancient people did and how their societies were organized to do it, this rueful characterization merely underscores the challenge confronting archaeologists who wish to learn from the past from its material remains. No one promised that it would be easy; fortunately, some have thought seriously about the problem in ways that might help us meet the challenge.

For instance, Cowgill (1970) described the archaeological record as the transformed, progressively diminished remnant first of what was deposited, then of what preserved among the deposits, and then of what could be found and recovered of those deposits. However mundane the argument may seem to outsiders, it focused archaeologists' minds on the steps in the process that separate living cultures of the past from the material record that we study now and led eventually to serious theorizing about how the record formed and the systematic transformation that structure it at each stage. Archaeologists called this "middle-range theory," "formation processes," "accumulations research," or "formation theory" (Shott 2006). In the 1970s, prominent American archaeologists debated what the record was. If to Schiffer (e.g., 1976) it was transformed ethnographic tableaux, Binford (e.g., 1981) saw all records as fundamentally different categories of evidence to ethnography's. To Schiffer, if we systematically account for transformations between ethnographic and archaeological contexts and more finely resolve past time, then we approximate the ethnographic record. Binford argued instead that not merely transformation and timescale separate the two records and that how they formed and what they revealed differed immensely. Like many debates this one gave off light but also much heat that sometimes obscured the good points that antagonists made. But at least it served to contrast archaeological and ethnographic data, a difference that, even now, archaeologists have assimilated imperfectly (Perreault 2019). In the process, it gave renewed emphasis to ethnoarchaeology, the study of living peoples and cultures for how they form their archaeological records. As a result, Binford but also many others documented how cultures of many places and characters generated their own archaeological records.

Briefly around 1980, ethnoarchaeology was popular, and it has continued since as a secondary but vital branch of archaeological theory and method (David and Kramer 2001). Just as ethnoarchaeology and formation theory began to gain traction in the 1970s and 1980s, however, their development was complicated by other intellectual trends. For reasons that had as much to do with contemporary sociopolitics and European, particularly British, intellectual reactions to American thought (Shott 2005) as with the past, a strain of postmodernism gripped archaeology in the 1980s. Somewhat subsided today, it nevertheless questioned legitimate archaeological concerns. For instance, postmodernists cited by David and Kramer (2001: 419) airily dismissed ethnoarchaeology as an immoral effort to deny peoples' or cultures' splendid isolation by subjugating them beneath general principles residing within bodies of thought like formation theory. In this view, there are different cultures, but no general patterns or causes of the undeniably immense variation among them. Instead, each culture must be contemplated only in its irreducible uniqueness. This is academic nihilism unworthy of serious regard and a brief for archaeology as glorified butterfly collecting.

Postmodernism also created the trope of record as text to be read to reveal its many voices and messages. In the process, many nouns became verbs, and words like "multi-vocality" grew popular among archaeologists who regarded the effort to learn about and from the past as a futile bourgeois pastime. In its place, reading the record reduced to exercises in cleverness or inscribing a blank canvas with one's intellectual predilections. In this climate, how the record formed either was irrelevant, or its systematic characterization was hopelessly confounded by ineffable systems of meaning accessible only to the living mind and therefore beyond the reach of any theory of a

material record whose producers do not survive to explain it. The latter is, at best, a clever counsel of despair. Record as text identifies archaeology's material record with written texts. In the process, it rests on a conflation of very different purposes and origins. All writers write for an audience; even diarists write for themselves. In contrast, only vanishingly small fragments of the archaeological record were deposited with the self-conscious purpose of interpretation by those expected to encounter them later.

Whatever the sources and origin of historical data, archaeology's is a record chiefly of what ancient people lost, abandoned, or discarded. The archaeological record, then, was not written for audiences; it accumulated as the by-product of actions, ordinary and extraordinary, and with no future readers in mind. As our only source of grounded knowledge about the remote past, archaeologists must properly recognize the material record as it is, not as their conceits may wish it to be: unintended consequence, not constructed text.

Despite such distractions, formation theory as a way to explain the record has made modest progress. One example of its contribution to understanding the archaeological record is formation theory's explanation of "discard behavior," where trash was placed, how, and with what other trash. This could be regarded either as trivial or impossible to know, but instead it was shown to pattern systematically with culture type, land use, and other factors (e.g., Murray 1980), whatever unethical subjugating of ineffable uniqueness entailed. And, far from being trivial, it matters a great deal to how we interpret the record in ways that range from the existence of "toolkits" (tools thought to be used together in performance of certain tasks and therefore to reveal the nature and frequency of ancient peoples' actions) to parsing the occupational history of complex sites (e.g., Varien and Ortman 2005; Chapman and Gaydarska 2007) with all its implications for population trends, political organization, and social process.

Another example concerns how we understand the abundance of things in the archaeological record. In an innocent past, the more abundant an artifact type was in the record, the more important was its role or frequent was its use in the past. Following such logic, future archaeologists might conclude that people today smoke cigarettes much more often than we wear expensive jewelry because butts are far more abundant than are diamond rings in the material record that we are accumulating. Correcting such misapprehensions draws our attention to an intervening factor – how long different things last in use or "use life" (Schiffer 1976: 60; Shott 2018) – and to systematic variation in this factor that must be understood as we interpret the record.

Current Debates and Future Directions

Would that there were many more examples and that formation theory and systematic study of the archaeological record qua evidence were actively debated today. Instead, in an archaeology that continues to lurch from fad to intellectual fad in its immature disciplinary state, formation theory and its critical role in explaining the record were left to languish somewhere between indifference and oblivion. Case studies cited above and others show that some archaeologists continue to study it seriously, but it no longer is a central concern of the field. One of our most urgent tasks is to establish the serious study of formation theory at what it pleases British academics to call the "high table." That is, archaeologists must regard formation theory not as an esoteric infatuation of the few but as an essential tool in every archaeologist's quest to learn about the past. If formation theory were vigorously debated today, topics might include the connection, if any, it implies between archaeology and anthropology and the relevance of the record and formation theory to the full range of general theories. In North America, archaeology is subsumed beneath anthropology in ways not duplicated elsewhere. Whatever purpose its encapsulated status may have served historically, today archaeology is poorly placed within an anthropology whose chief preoccupations are vastly different from ours. Formation theory and the nature of the archaeological record, as complex, time-averaged accumulations rather than simple ethnographic tableaux (Perreault 2019), sharply distinguish archaeology from an anthropology that requires neither. Archaeology also applies a range of general theory that differs in

character and epistemological status from the interpretive traditions that most anthropologists practice. Perhaps if and when archaeology achieves in North America the disciplinary independence that it has deserved for at least decades, formation theory will rise in importance and stature.

Whatever the complexities of its formation and the obliqueness of the prehistoric action that it registers, the archaeological record is our sole evidence of the cultural past. Of course how we interpret the record depends crucially upon how we understand its formation. But how we understand the past depends also on how we explain the action, structure, and process that the record preserves; formation theory and general theory are equally essential to archaeological research (Shott 2006). Accordingly, the understanding of how the record formed is not confined to theoretical traditions like materialism in its various guises. Rather, formation theory is equally vital to all theoretical traditions, including those that favor agency, symbol, or structure over material conditions. In its most radical programmatic statements, the postmodernism noted above denied the possibility of knowing the past and, by extension, the need to ground inference in evidence. Such views neatly reduce archaeology to the "irresponsible art form" that Clarke (1973:16) feared it might become. But the excesses of postmodernism at least inspired the belief that the past might be understood in structural and symbolic terms, not just in the material terms of what people ate or did. At length postmodernism yielded to more constructive cultural and structural theories that provide balance to the materialism that undeniably dominated archaeological, particularly American, thought in processualism's heyday (Roux 2007).

Today, nonmaterial theory is both more diverse and, in significant degree, committed to grounded inference (e.g., Chapman and Gaydarska 2007). Warts and all, such theory considers not just material conditions and individuals or groups as strategizing agents but also intrinsic cultural context which, admitting only the possibility of systematic properties to cultural variation, therefore is accessible to both general and formation theories. To date, however, there has been more development of general cultural theory than the "middle-range (i.e., formation) theory of mind" (Cowgill 1993), of structure, and of organization that is as conceivable and essential as it currently is neglected. Sources like Hill (1995) and Chapman and Gaydarska (2007) are exceptions that prove the rule; cultural theory awaits the formation theory that can make its inferences reasoned, not a priori.

A start has been made using ethnoarchaeological study to illuminate social, political, and symbolic dimensions of cultures. The Colombian Nukak, for instance, deliberately break artifacts during dispute resolution (Politis 2000). Awá men of the Brazilian Amazon make arrows out of proportion to their utilitarian value; details of fletching, construction, and use are signifiers of maleness, not mere functional attributes, and "use" sometimes amounts to little more than carrying arrows (González-Ruibal et al. 2011). Applied mechanically to archaeological interpretation, these observations are mere cautionary tales (e.g., that the abundance of arrows in material records may not directly measure the frequency or importance of hunting) that underscore the often particular cultural contextualization of the record's formation. But compiled into a larger body of evidence itself synthesized as Cowgill's "middle-range theory of mind," they can reveal symbolic dimensions in the use of material objects and their discard into the record. In this way, formation theory is not narrowly material or utilitarian but broadly cultural in its scope.

Yet concerning formation theory, there is room for improvement in all varieties of archaeology's general theory. We have no shortage of general theoretical stances and predilections, most of which are inadequately grounded in evidence by a sincere effort to develop necessary formation theory. Varieties of evolutionary theory, for instance, have resurged since the 1990s (e.g., O'brien and Lyman 2000). Context in the record does not figure prominently in their usage; also, they sometimes dismiss formation theory as an effort to reconstruct ancient behavior, which they reject on principle as unobservable. Yet every evolutionary invocation of transmission, style, drift, and function invokes behavior, at least implicitly; more broadly, formation theory and the

understanding of the record's meaning that it provides are as essential to evolutionism as to any other general theory in archaeology. Similarly, intellectual traditions in classical and prehistoric archaeology are quite distinct, yet formation theory was central to Peña's (2007) study of Roman pottery.

Conclusions

Even in archaeology's present underdeveloped state of intellectual development, it is futile to debate what the record is; at least broadly, we agree on that score. Nor should we wonder if it preserves all relevant detail and content of all past cultures. Of course it does not. Yet it is equally futile to suppose that the record is so limited and biased as to deny the possibility of systematic, fairly far-reaching inference to those past cultures or to free archaeological thought from any grounding in relevant evidence. The archaeological record is neither our best friend nor worst enemy. The archaeological record simply is. It is for us to determine what can be made of it.

Case Studies

Despite halting advances and sometimes bitter debate, archaeologists of various theoretical casts have used formation theory intelligently to improve their inferences from general theory and their understanding of the past generally, encouraging signs that serious study of how the record formed is regaining traction. Hill (1995) interpreted patterns and sequences of discard at British Iron Age settlements in symbolic terms, as ritual or "structured deposition" that revealed elements of world view. Careful analysis of deposits and building sequences at a Cypriot Bronze-Age village allowed Frankel and Webb (2001) to estimate population size and occupation span and gave insight into household size and structure and social reproduction otherwise obscured from view. Gallivan (2002) examined joint variation in population and sociopolitical complexity in the late prehistory of the American mid-Atlantic coast. Varien and Ortman (2005) used formation theory to determine occupation span and sequence of Puebloan villages in the American Southwest, which they then linked to land tenure, economic intensification, and sociopolitical trends. Lamenting neglect of "how and when different kinds of pottery came to be incorporated in different amounts and in different conditions into different kinds of archaeological deposits" (2007: 1), Peña demonstrated the relevance of formation theory in Roman archaeology. Shott (2018) compiled a large dataset on Mexican Purépecha pottery uselife, some derived from near-monthly household censuses, and fitted it to Weibull models. Results showed not only differences in mean uselife by vessel type and size class, but graded variation in Weibull attrition coefficients. Purépecha data also patterned with a global sample of census-derived pottery uselife data, revealing robust patterns that allow analysts to predict uselife from easily observed measures of vessel size in any cultural context. Surovell (2009) both integrated formation theory with a general theory, behavioral ecology, and applied it systematically to stone tools and debris, among archaeology's most abundant and widely distributed materials.

Archaeological Research in Colonial Angola

Bruno Pastre Máximo
Laboratório de Arqueologia e Estudo da Paisagem, Universidade Federal dos Vales do Jequitinhonha e Mucuri,
Diamantina, Minas Gerais, Brazil

Introduction

The development of archaeology in colonial Angola can be divided into two moments. The first moment relates to the work conducted by foreign and Portuguese archaeologists involved with the diamond exploration company Diamang in the Lunda region. Also in this period, there was work conducted by colonial agents, especially in the Angolan Anthropological Missions which took place in the 1940s and 1950s. It is worth mentioning that both of these efforts were aligned with the colonial project, be it in a indirect or direct form. The second moment is marked by a change in the line of research, seeking a distancing from colonial ideology, incorporating the matter of teaching and professionalization of archaeology in the colony, while still trying to incorporate African narratives in the interpretation of the material analyzed.

Key Issues

The inaugural works on the prehistory of Angola date back to the year of 1890, with the publications of Servero and Nery Delgado. Afterwards, the explorers Serpa Pinto, together with his assistant Santos Júnior, conducted some surface collecting and interpretations in the 1930s. Santos Júnior, when returning to Portugal, organized a synthesis of the explorer's works on the prehistoric past of Angola, presenting it in the 1934 *Congresso Nacional de Antropologia Colonial do Porto*. The presentations reinforced the connection of the studied pieces with the Tumba culture, existent in what was at the time the

Belgian Congo. Up until the 1940s, studies consisted mainly in describing isolated pieces, found on the surface, seeking more to establish a classification and chronology of an object regarding cultures at the time than an analysis per se.

The first substantial works of archaeological research in Angola begun based on the initiative of the DIAMANG company (*Companhia de Diamantes de Angola*), in mid 1930s. The company was given concession by the colonial government of an area of over 30,000 km^2 in the Lunda region, for the exploration of diamonds. With the expansion of profits, the company began making cultural investments that led to the hiring of researchers and scientists, culminating in the founding of the first museum of Angola in 1936, the *Museu do Dundo* (Porto 1999). The purpose of the creation of the museum was to preserve the traditions, which were "lost in contact with civilization."

A sagacious collecting of material was therefore initiated in the region, with a leap from 496 objects in the collection in 1936 to 5500 in 1942. Under the curatorship of José Redinha, the museum expanded, creating new departments; among these is the archaeology and prehistory department which was idealized by the technicians employed by the company, namely, the archaeologists and geologists – J. Redinha, Fernando Mouta, Jean Janmart, H. Breuil, L. Leakey, J. Camarate França, and Desmond Clark (Porto 1999). This group was favored by the profile of the Diamang and the museum which, even though aligned with colonialism, had the autonomy to conduct research with the presence of foreigners, resulting in an assemblage of objects obtained in different ways: surface collecting, collecting through mining activity (both in the extraction as well as in the washing and separation), and archaeological excavations (Domingos 2009).

Numerous efforts were made in the region, culminating in a series of published articles in the *Publicações Culturais do Museu do Dundo*, which became an important instrument in the establishing of international partnerships with renowned academic institutions. Thanks to the work of these specialists, the northeast region of Angola is one of the most well-known in the Zaire River basin region (Ervedosa 1980).

The main efforts were the ones developed at first by Janmart and later continued by Desmond Clark. During his stay, Clark undertook important studies for the understanding of the prehistory of the region, also being a critic of nomenclatures and chronologies attributed to the Angolan territory (Clark 1971). The author's reference works are those that he proposes a synthesis of his activities and the confectioning of an archaeological letter (Clark 1963, 1966; Clark and Langeheim 1968).

Parallel to the activity of researchers connected to Diamang, the Portuguese State also sought to obtain more information on the past of the native inhabitants of their domains. Ever since their origins, these investigations already possessed a character notably centered on physical anthropology. The connection of physical anthropology to archaeology is understood regarding evolutionistic aspects existent at the time and consolidated in what was called the *Escola do Porto*.

This school of thought, according to Pereira (2005), guided the course of Portuguese anthropological thought, especially in the first half of the twentieth century, and one name would mark an entire generation of studies involving anthropology and archaeology: Antônio Augusto Mendes Corrêia (1888–1960). His career began in medicine, followed by a doctorate in physical anthropology in 1921, already assuming an important role in the University of Porto (*Universidade do Porto*), as professor and cathedratic of anthropology of the *Faculdade de Ciências Naturais*.

In the first half of the twentieth century, Portugal lived a situation not only of economic hardship but also of a violent political repression, where freedom of thought was persecuted and condemned and the incentive for research was reduced. This situation would change from the 1940s onward with the consolidation of the *Junta de Investigação do Ultramar* (JIU).

The emergence of the JIU happened in the mid-1930s, in the heart of a debate on the precarious situation in which studies regarding the Portuguese colonies were found at the time. The vision on the role of science was directly related

as a form of guaranteeing success of the colonization and the exploration of colonial resources (Castelo 2012). In this initial moment, archaeology appeared as one of the branches of anthropology, following the notion of anthropology by the *Escola do Porto*. The concept incorporated at the same time racial theories and aspects from physical anthropology, in this case the prehistory of populations, being absent of social or cultural perspectives (Pereira 2005).

In the anthropology and archaeology area, Mendes Corrêa elaborated in 1940 a study plan for colonial anthropology. In this plan, according to Poloni (2011), Corrêa established a hierarchy of research priorities, with a privilege toward physical anthropology, as a way to measure and evaluate the physical conditions of the Africans relating to work force. Archaeology would occupy a smaller space, losing importance, maintaining the interest solely in the scholarly part, so as Portugal would not distance itself from the international debates.

For Poloni (2011), archaeology only maintained itself in the anthropological missions due to four reasons:

1. The need for interaction with the international scientific panorama.
2. Exchanges with important figures from national and international archaeology.
3. Archaeology is used as a way to evaluate the potential of each native community based on knowledge of their past.
4. Through anthropobiological fieldwork, the same resources are used in order to conduct archaeological reflections according to the time and space available.

The anthropological missions were carried out in the period between 1945 and 1975, with a total of 21 incursions, comprising the colonies of Moçambique, Angola, Guiné, and Timor. To Angola, four campaigns were undertaken in the years of 1948, 1950, 1952, and 1955. The chief of the missions was the physician Antônio de Almeida (1900–1984). In his campaigns in Angola, he travelled over 45,000 km, registering aspects such as behavior, dressings, material culture, kinship relations, religion, and demography among the country's different ethnic groups.

It was exactly in the missions to Angola that the paths of the Diamang archaeologists and that of Almeida crossed. Since the first mission in 1948, Almeida counted with the support and collaboration of Diamang members in order to conduct his studies on the prehistory of Angola. In an initial moment, he worked with Camarate França in various sites, until his death in 1962, being replaced with Henri Breuil.

All efforts related to archaeology were published in the periodical *Memórias da Junta de Investigação do Ultramar*, between the years of 1950 and 1964. The missions' efforts were, as oriented, directed toward anthropobiological questions, giving little attention to activities related to archaeology (França 1960). This critic was reflected not only toward the preponderant character of physical anthropology but also its obsession by the ideologists of the *Estado Novo* and Mendes Corrêa. According to the research program of the anthropobiological missions, the studies on physical anthropology occupied around 75% of the fieldwork activities undertaken, leaving activities related to the research and gathering of data and spoils in the domains of ethnography, of prehistory and archaeology to use only around 25% of the determined time for each campaign (Rodrigues 1999).

Despite the relative little interest toward archaeology, we can see some very positive and controversial results from some of the missions. Among the many studies published, analyses on archaeological vestiges were presented, such as those which seeked to create typologies for the lithic industry of Angola and attempted to create chronologies, trying to insert artifacts in a regional and international perspective. Almeida sought in some of his analyses to reinforce notions already rejected at the time, such as that of European diffusionism, attributing a European origin to structures considered as of high complexity, located in the interior of Angola, such as the walled enclosures existent in the south of Angola, in Huila region.

As a summary of this phase of Portuguese archaeology in Angola, we have the participation

of Almeida and the French archaeologist Henri Breuil, at the *Congresso Pan-africano de Pré-história e Estudo do Quaternário* (Leopoldville 1959). The two authors seek to resume the state of Angolan archaeology and contextualize it regarding work done in the continent (Almeida and Breuil 1964).

The controversial positions of the colonial authors were a symptom of the state of Portuguese archaeology and its primordial involvement with the political cause, to the detriment of technical and scientific questions. By privileging anthropobiological studies, colonial archaeology in Angola up to that point skidded over elementary questions with the intention of sustaining a colonial regime in decadence and which was losing its references for existence. In the Portuguese, colony studies resumed themselves to prehistory with a racialized and evolutionistic inspiration. The obsessively biological dominance of anthropology and also of archaeology, according to Pereira (2005), blocked an analysis directed toward social and cultural questions in the anthropological missions, contributing to a classification of the colonized people as inferior races. The major objective of these "scientific" incursions was to provide the Salazar regime with arguments which would justify the maintenance of the status quo and the empire, based essentially on the decadent concept of "inferior races" and on the contrast between "barbarian and civilized."

With the death of Mendes Corrêa, the *Junta de Investigação do Ultramar* underwent significant changes, putting aside the perspective of physical anthropology in exchange for a more ethnological bias. In the case of Angola, it is important to point out the arrival of the anthropologist Santos Júnior – chief of the anthropobiological missions of Mozambique – to the University of Angola, located in Luanda and the founding of its department of anthropology in 1970. Archaeological teaching and research began on that same year, ministered not only by Santos Júnior but also by the writer Carlos Ervedosa, a great enthusiast of the Angolan past. His involvement with archaeology began in 1967 with the work conducted in the paleolithical sites of Baia Farta, in Benguela. After the arrival of Santos Júnior, a partnership was initiated between him and Ervedosa, resulting in work conducted in Benfica I Cobolombo, in the outskirts of Luanda, and on the rock paintings of Caninguri, in Mungo (Domingos 2009).

The archaeology classes at the *Universidade de Angola* produced very interesting results, as demonstrated by the article published by Jorge in 1974, where there can be found listed a great amount of sites discovered in the southwest of Angola on that same year. Vitor Oliveira Jorge, who was at the time professor of archaeology, discovered in 1973 during fieldwork an area with a large amount of objects, including a cemetery. The place went on from a simple archaeological site to being an object for teaching, something unprecedented in the colony.

This union between research and teaching was something innovative among the students of the colony. Despite the delay in the establishment of universities in the colonies, this was an important step for the development of archaeology on the territory, since the purely ideological and political interest of anthropology was withdrawn, bringing a perspective with a more scientific and cultural rigor. The reality altered itself, now problematizing more on scientific colonial practice, incorporating new points of view not necessarily connected to the state.

In this new phase of Portuguese colonial science, the research of Jorge and others was also innovative in two other aspects: it presented a critical reflection about the work previously carried out in Angola as well as the incorporation of historical and ethnological reports in his analyses. Jorge and others, even though inserted in the colonial structure, were able to establish some critics regarding work conducted in previous studies. His work on Angola can be found summarized in the text *Breve Introdução a Pré-História de Angola* (1975). Santos Júnior also contributed in an important way by conducting a wide research on the rock paintings in Angola, which resulted in an article in which he comments on his findings and possibilities for research (Santos Júnior 1974).

When studying the vestiges on earring cast molds found in an ancient city in the north of Angola and Quibaxe village, Rui de Sousa

Martins took advantage of the involvement with the traditional chief of the locality and gathered information on the use of earrings by the people of the region and what were the meanings attributed to them. Furthermore, he registered with detail the entire procedure used in the making of earrings, from the objects used up to the techniques and forms of preparation (Martins 1982).

Analyzing the methodology used by Martins, we can observe a change in Angolan archaeological practices when compared to the previous period. The registering and adoption of the local chief's knowledge regarding the artifact were not only an act of consideration but also a break in hierarchy, where the importance of the chief's wisdom was recognized and given the opportunity to him of interpreting and contributing to the archaeological interpretation. It also showed an interest, before absent, on the recent past of the people of Angola, the so-called people of the Iron Age. His work, together with those of Ervedosa, Oliveira Jorge, and Santos Júnior, marked the end of studies characterized by colonialist ideology in Angola, with the effective rupture in political terms occurring in 1975 with the declaration of independence.

Archaeological Resource Management: The Changing Role of the State

Roger M. Thomas
English Heritage, Swindon/Wiltshire, UK

Introduction

In the United Kingdom (as in many other countries) the state, from the end of the Second World War onwards, played a dominant role in investigating, protecting, and presenting the nation's archaeological heritage. Now, in very many areas of life, the role of the state, and the relationship between citizen and state, is changing. Archaeology, and also heritage protection more generally, are affected by this in a variety of ways. The way in which state archaeological organizations operate in the future may be rather different than it has been in the past.

Key Issues/Current Debates/Future Directions/Examples

In 1945, immediately following the end of the Second World War, the Labour Party came into government in the United Kingdom, following a "landslide" victory in a general election. This marked the beginning of a phase of history in which, under the so-called "welfare state" philosophy, central government played an increasingly dominant role in many different areas of the life of the nation. The same trend was seen, in varying degrees, in many other liberal democracies in western Europe and beyond.

The investigation and protection of the archaeological heritage, and the presentation of this heritage to the public, was just one among many areas of activity in which the role of the United Kingdom state expanded greatly in the decades after 1945. Central government and its agencies undertook extensive archaeological surveys; new legislation was introduced to provide better protection for archaeological sites and monuments; officials selected more sites for such protection; greatly increased finance was made available for excavating sites threatened with destruction by development; important monuments were excavated, conserved, and displayed for the benefit of the members of the general public who wished to visit them; and guide books, produced and sold by the state at the monuments, gave authoritative accounts of the remains and their interpretation. One result of all this activity and expenditure was the development of a substantial archaeological profession. Another was the establishment of a particular kind of relationship, in the area of archaeology and archaeological protection, between the state and the archaeological profession on the one hand and interested members of the public on the other. The state was a major provider of interpretation and narrative (in a broad sense, and not least in the kinds of monuments and remains which it chose to investigate and protect), and the public was cast largely in the role of passive consumer of messages devised by officials of the state and archaeological professionals dependent on the state (Thomas 2004: 192–3).

Today, the situation is very different. The role of the state has changed quite significantly in recent years and is continuing to change. There is every indication that the rate of such change may, if anything, accelerate in the coming years.

There are many reasons for this. Globalization, the Internet, and the emphasis on "consumer choice" have made people much less ready to accept single, "official" versions of the nation's past. Increased leisure and mobility (for some, at least) have prompted people to find new ways to spend time. The digital social media are leading people to expect to contribute their own views (and to have these listened to) rather than simply being passive consumers of information and decisions emanating from the state and other large corporate bodies (Thomas 2004: 193–5). Most recently, the economic crisis which has engulfed large parts of Europe since about 2008 has left many governments struggling financially. Many states are cutting their expenditure drastically; in the future, they will not be able to provide all the things which they have been providing in the recent past.

This, then, is the broad background to this entry. Two main forces for change can be identified. First, people are much less ready and willing today to simply accept the authority of the state without question; people wish to decide for themselves what they believe, and they also want their voices to be heard by authority. Second, the state is less able to provide services (of many different kinds) than it was previously. The archaeological functions of the state are no exception to this; indeed, they may be among the more vulnerable because these functions can easily be seen as less necessary than, say, health or education. It is easy to see how these two trends can reinforce each other.

How, then, are these trends being manifested in archaeology and heritage protection in the United Kingdom today? And how are state archaeological organizations and their officials reacting to them?

The rejection of "official" views of the archaeological past can perhaps be seen most clearly in the way in which prehistoric archaeology and prehistoric monuments have been taken up by "New Age" and "pagan" believers. The conflicts over access to Stonehenge are well known (e.g., Bender 1998), but there are other examples of contest over the rights to, and interpretations of, prehistoric monuments. A particularly telling episode occurred when a prehistoric timber circle was exposed by storms on a beach in Norfolk in the east of England. The monument was quickly labeled "Seahenge." English Heritage (the principal state agency for archaeology and heritage in England) believed the monument to be at risk of destruction. It decided that the best course of action would be to investigate the monument scientifically (in the course of which some physical damage would be caused) and to remove the timbers from their context in the hope of preserving them elsewhere. The state was seeing the monument primarily as a resource for scientific inquiry by dissection. Other groups, however, had different ideas. Pagans of various kinds believed that the monument was a sacred place and should be left in peace. The conflict was acute and generated a huge amount of media coverage (Champion 2000).

Seahenge was an example in which the beliefs and perspective of a particular group clashed with those of the state. In other cases, a group may simply develop its engagement to the past with little or no reference to what the state thinks (if anything) of that group's perspective. "Pagan" or "alternative" uses and interpretations of ancient monuments (particularly prehistoric ones) are an example of this (Cope 1998).

Thus, in some instances the authority of the state may be challenged; in others the state is simply ignored because it is not seen as relevant.

Shifting power relations can be seen very clearly in the relationship between the media and the state. The television archaeology series "Time Team" has been immensely popular in England (and more widely) (Taylor 1998). It portrays archaeological investigation as a rather breathless pursuit, carried out by people who some might regard as slightly eccentric. In some cases, Time Team has wished to work on protected monuments, meaning that English Heritage's agreement has been needed. The relationship has not always been an easy one. Sometimes English Heritage has had reservations about what was proposed and has ended up being made to look slightly officious in the broadcast program. However, the public popularity of Time Team and its impressive viewing figures (routinely in the millions) have meant that English Heritage has not

wished to be uncooperative towards the program and its makers.

Overall, certain wider social trends – a readiness to reject "official" versions of the past in favor of alternative ones, to challenge state authority, and to pursue different agendas from those advocated by the state – are reflected in the public's approach to archaeology and heritage. There is no doubt that responding to these trends poses considerable challenges for state archaeological and heritage organizations, accustomed as they are to "top-down" ways of seeing the world and of operating. How have such organizations tried to respond?

"Designation" (protecting buildings, monuments, and areas by giving them specific legal protection) has long been a key state function. Traditionally, decisions about which monuments to select for designation were made by officials, using criteria which reflected a particular outlook and set of priorities (Thomas 2004: 192–3). In recent years, a number of things have happened. First, English Heritage has encouraged members of the public to propose sites for designation and has provided a means of doing this online. Second, the idea of "local listing" – that is, designation at a local level, by local authorities, using locally developed criteria – has been promoted. This is seen as a more locally responsive system than one operated entirely by central agencies. In theory, "local lists" are meant to supplement national designation, allowing things which would not meet the stringent national selection criteria to be given some formal recognition, but it is possible that some locally listed items will be ones which are of national importance, but which central government has not yet had the resources to designate at national level. Third, English Heritage has undertaken a number of programs to assess the material legacies of "underrepresented" groups in England (English Heritage n.d. a, b, c).

Another interesting development has been the Portable Antiquities Scheme, in which public funding supports professional archaeological staff who record objects found by metal-detector users and other members of the public (Portable Antiquities Scheme n.d.). In England, there is no obligation on finders to report archaeological discoveries (other than those which fall into the restricted category of objects which are legally defined as "treasure"), so the scheme is very much about professional archaeologists reaching out to the public and working with them. Relations between professional archaeologists and metal detectorists have sometimes been uneasy in the past. When metal detecting first became widespread, some archaeologists wished to see it made illegal. That was never likely to happen (and certainly will not happen now), so engaging with metal detectorists has been the only viable option. In fact, many detectorists are deeply interested in the past and have a strong desire to be involved in its discovery but have chosen metal detecting, rather than (say) going on organized excavations, as their way of doing this.

Another recent growth area has been community archaeology (Council for British Archaeology n.d.). This is a large topic, but the broad thrust is clear – it is about nonprofessionals engaging actively in archaeology themselves and about some professionals acting as trainers and enablers, helping nonprofessionals to carry out archaeological projects which are of direct interest to them. One of the sources of funding for community archaeology is the Heritage Lottery Fund (which distributes fund raised by the National Lottery, established by the state in 1994). Of particular interest is the Community Archaeology Bursaries Scheme, under which the Heritage Lottery Fund and the state archaeological bodies for England, Wales, and Scotland support training placements "to equip would-be community archaeologists with the skills, experience and confidence to work with voluntary groups and communities." The message is clear – rather than the state doing archaeology on behalf of the citizen, it is helping the citizen to do archaeology on behalf of himself or herself.

All of the forms of activity described above are reflections of a changing relationship between state and citizen in the area of archaeology and of changes in the way the state operates, made in response to this changing relationship. Citizens are no longer so willing to be the passive consumers of messages generated by state-employed professionals, and the Internet and social media provide new and larger opportunities for the

citizen to make his or her voice heard and to exchange views and information directly with other citizens. At the same time, the state's ability to do everything itself is declining, which makes it difficult for professionals to argue (even if they wanted to) that archaeology is best left to the state and the professional to do.

In many ways, what is happening in archaeology in the United Kingdom today is a microcosm of what is happening in society more widely: a public which expects to have its views listened to by the state, a state which cannot afford to do everything which it might like to do or which it used to do, and a voluntary sector which is starting to show signs of filling some of the gaps left by the state. The activities described above are all examples of new kinds of relationships being negotiated between the state and the citizen, in a world which is changing rapidly and which is already markedly different from that of the "welfare state" which emerged after 1945.

There is no doubt, of course, that the state will continue to play a very important role in archaeology in the future. Not least, the imposition of legal controls on private property is something which can only be done by, or with the full backing of, the state. Nonetheless, it is clear that the role of the state in archaeology, and the relationship between citizen and state in this area, has changed substantially over the past 20 or so years. It seems beyond doubt that it will continue to do so in the years and decades ahead.

Archaeological Review from Cambridge

Skylar Neil and Victoria Pia Spry-Marques
Department of Archaeology, University of Cambridge, Cambridge, UK

Brief Definition of the Topic

The Archaeological Review from Cambridge (ARC), first published in July 1981, is a biannual academic journal of archaeology, with calls for papers released approximately 18 months before its two publication dates (April and November) (Fig. 1). It is run on a nonprofit, voluntary basis by postgraduate students at the University of Cambridge. The present Committee is comprised of members working on such diverse research projects as Croatian Epigravettian subsistence strategies and Etruscan identities.

Rooted primarily in archaeological theory and practice, publication in ARC is open to all, and it increasingly invites a wider range of perspectives

Archaeological Review from Cambridge, Fig. 1 Cover of the April 2012 issue of the Archaeological Review from Cambridge

with the aim of establishing a strong, interdisciplinary journal which will be of interest in a range of fields. Recent issues have focused on such topics as violence in the material record, boundaries and archaeology, and economic crises:

- volume 26.1 (April 2011): *Archaeology and Economic Crises*. Edited by Suzanee E. Pilaar Birch and Rosalind Wallduck
- volume 25.2 (Nov. 2010): *Boundaries and Archaeology*. Edited by Mark Sapwell and Victoria Pía Spry-Marqués
- volume 25.1 (April 2010): *Violence and Conflict in the Material Record*. Edited by Skylar Neil and Belinda Crerar

Current issues under production include Katie Hall and Danika Parikh's (eds) *Science in the Material Record* (27.1 – April 2012), which looks at how advances in archaeological science have opened up new vistas when it comes to the interrogation of archaeological material in the twenty-first century, and Dominic Walker's (ed.) volume on *Collaborative Archaeology*,

due to be published in November 2011 (issue 26.2).

Archaeological Soil Micromorphology

Richard I. Macphail
Institute of Archaeology, University College London, London, UK

Introduction

Archaeological soil micromorphology, which has become increasingly developed as a technique over the last 70 years, is now a major global component of geoarchaeological investigations. This is because it not only provides information for landscape studies but is best able to identify site formation processes, land use such as numerous types of cultivation, and use of space within houses and settlements (Lee et al. 2014). Key to this is the recognition that soils and sediments are not only worthy of contextual study but also that being artifacts they are a fundamental part of the archaeological record.

Definition

Archaeological soil micromorphology is adapted from soil science and geology using thin sections and the polarizing microscope, where undisturbed soils and sediment samples are stabilized by resin impregnation before thin sectioning. This method has now become developed specifically in order to investigate soils and sediments affected or produced by humans; the latter includes a wide variety of archaeological materials. The technique employs the use of standard optical (plane polarized light [PPL], crossed polarized light [XPL], and oblique incident light [OIL]) and fluorescence (e.g., ultraviolet light [UVL], blue light [BL]) microscopy, as well as instrumental studies on thin sections, such as scanning electron microscopy (SEM), energy dispersive X-ray spectrometry (EDS), microprobe, micro Fourier transform infrared spectroscopy (micro-FTIR), and micro X-ray fluorescence (micro-XRF). Methods and applications have developed especially over the last 30 years with standardized descriptive and various numerical methods and the employment of such geological concepts as "microfacies" and a hugely enlarged reference base (Bullock et al. 1985; Courty et al. 1989; Courty 2001; Goldberg and Macphail 2006; Macphail and Goldberg 2018a; Nicosia and Stoops 2017; Stoops et al. 2018).

Historical Background

Ian Cornwall, Institute of Archaeology, University College London, UK, was the first person to apply the new technique of soil micromorphology as developed by Kubiena (1938) when working with Frederick Zeuner, the first ever professor of Environmental Archaeology. Cornwall contributed numerous analytical reports on British and foreign archaeological sites during the 1950s and 1960s (11 are cited in a review of soil science in English archaeology; Macphail 1987). For example, Cornwall provided a barrow-buried thin section study on the classic Neolithic cultivated site of Kilham, North Yorkshire, when working with major environmentalist archaeologists (Dimbleby and Evans 1974). These first investigations were followed up by the Scottish soil scientists Romans and Robertson (Macaulay Institute, Aberdeen), who when providing analytical data on Scottish soils managed to investigate a number of

monument-buried soils dating to the Neolithic and Roman periods, with special focus on environmental change and ancient cultivation (Romans and Robertson 1983).

The next major advance came in an international collaboration, which considered that the current understanding of soil science and geology could be applied to the soil micromorphological study of archaeological soils worldwide; this was done through a series of thematic chapters and case studies in "Soils and Micromorphology in Archaeology" (Courty et al. 1989). The authors had the great benefit of the advice of internationally famous soil scientist Nicholas Fedoroff (Institut National de la Recherche Agronomique – INRA; Paris-Grignon, France). Subsequently this methodology has continued to advance through experiments, the increased employment of associated instrumentation and closer collaborations with other scientists (e.g., soil chemistry, macro- and microfossils) studying the same soils and sediments (Cruise et al. 2009; Viklund et al. 2013; Linderholm et al. 2019). As archaeology has now often come to rely on the data that thin section studies can provide, the number of workers in this field has expanded exponentially, while the number of soil micromorphologists working in agronomy has shrunk dramatically. High standards have in part been encouraged by the establishment of the Working Group on Archaeological Soil Micromorphology in the early 1990s. Important advances have also been made by taking part in long-term archaeological experiments such as the Experimental Earthworks Project and Butser Ancient Farm in the UK and at Umeå University, North Sweden, and by extemporizing experiments and employing ethnographic analogue sites to examine specific questions across Europe and Africa (see Banerjea et al. 2016; Goldberg and Macphail 2006; Mallol et al. 2017; Shahack-Gross 2011).

Current Themes of Study

The number of ways that soil micromorphology contributes to archaeological investigations is ever-increasing. In the first instance, these relate to attempts to match pedological and/or sedimentological formation processes with human occupation, whether in open air sites or in caves, for example. In many cases, these formation processes are simply contemporary and not influenced by human activity. Such studies can only be carried out if there is a very clear understanding of the processes that effect *buried soils* and *sediments*. It also has to be remembered that during the Pleistocene and at sites affected by human-induced colluviation, surfaces may be ephemeral and pedological development is likely to be very weak. Here, we are dealing with *soil sediments*. In some cases, sites have been preserved by sediments associated with alluviation and/or marine inundation, and here not only are these events required to be recognized, but also their effects on buried surfaces need to be understood. Thus, *inundated sites* necessitate comprehension if microfeatures now present in buried landscapes are to be interpreted properly.

Another key area is the study of *archaeological materials*, and these include everything from human latrine waste and animal coprolites to constructional and industrial materials. In terms of major human impact on the landscape, *clearance* and *cultivation* are often of primary importance and require accurate identification. Closer analysis of complex societies however also warrants a clear idea of how *occupation surfaces* reflect use of space by humans and stock, but this is only one part of how *settlement morphology* can be elucidated. There will also be water holes and wells, graveyards, and middening areas, for example. Lastly, *site transformation* studies show how once recognizable occupation layers and farmed soils, for instance, became reworked after abandonment or through a land use change. This is a key aspect of investigation on any archaeological site. In fact, there has been a major focus on these kinds of studies on some of the most challenging archaeological deposits worldwide, such as European Dark Earth and Amazonian Dark Earths (e.g., *terra preta*; Arroyo-Kalin 2017). These eight themes which are discussed in detail elsewhere (Macphail and Goldberg 2018a) are now briefly presented.

Issues concerning how *buried soils* and *sediments* could be accurately interpreted were first

addressed by soil micromorphological components in the Experimental Earthworks Project, UK, both on base-rich chalk soils (Overton Down, Wiltshire) and on acid soils (Wareham, Hampshire) (Macphail and Goldberg 2018a, 100–109). The chief result was the recognition that changes and compaction occurred rapidly after burial, especially at Overton Down, where an open, rooted, and earthworm-worked Mull horizon was transformed into a compact soil. In places, earthworms had migrated upward blurring the buried soil boundary. Compaction was in part due to a loss of organic matter (roots had disappeared or been finely fragmented) – as also shown by soil chemistry. The nature of soil burial is thus very important, and conditions of burial vary according to pH, degree, or absence of waterlogging and/or periodic anaerobism, extant soil fauna, weight of overburden, migrating solutions, etc. Neolithic chalk soil examples include the Rendzinas below Neolithic Easton Down and soil dump which formed the Neolithic bank barrow at Maiden Castle, Dorset, which encouraged earthworms to burrow downward into the buried soil; chalky soil burrow fills were in stark contrast to the original decalcified buried soil (Macphail and Goldberg 2018a, 109–113). In the case of the Gokstad ship burial mound, Vestfold, Norway, the anaerobic conditions which preserved the wooden long ship also encouraged the migration of phosphate within the turf mound. Vivianite became concentrated along some plant litter layers within the turf stack (Figs. 1 and 2) (Macphail et al. 2013).

Although an aspect of European prehistoric and historic colluvia is an outcome of clearance and/or cultivation, *soil sediments* are more often encountered in Pleistocene sequences, where these deposits can bury palaeosols or form palaeosols. Investigations of palaeosols with associated artifacts should always pay attention to the provenance of bones and stone tools, as concentrations of such materials can simply be the result of geological processes rather than cultural activity. Accurate interpretation is even more crucial at early hominid sites. The micromorphology of soil sediments and associated palaeosol formation, in relationship to the erosion of unstable soils, for example, has been investigated for a long time (Fedoroff et al. 2018). Climatic conditions, especially those involving cycles of freezing and thawing, have come under special scrutiny, especially in North West Europe and North America.

Archaeological Soil Micromorphology, Fig. 1 Late Roman Leicester, UK (Freeschool Lane, dark earth deposits); photomicrograph of lead (Pb) droplet embedded in calcitic ash, recording an earlier period of artisan activity – perhaps lead pipe soldering. This Context 6450 is generally strongly enriched in lead (2560 μg g^{-1}), a common metal on Roman sites (analysis by John Crowther, University of Wales Trinity St David) (Macphail and Goldberg 2018a). Plane polarized light (PPL)

Cave sedimentology has also improved our understanding of natural geological and faunal processes and its ability to differentiate sedimentary layers that are strongly influenced by human activity (Karkanas and Goldberg 2018). For example, mudflows occur beneath sink holes in caves, bird and bat guano strongly affect phosphatization, while large animal scavengers might burrow into "middens" and deposit coprolites. Diffuse hearth deposits are often termed combustion zones because of fragmentation by wind, water, and human and animal activity (Mallol et al. 2017). Recent micromorphological work on caves has been applied to site formation studies

Archaeological Soil Micromorphology, Fig. 2 As Fig. 1, under oblique incident light (OIL). Thilo Rehren, University College London (employing a metallurgical microscope), tentatively identified pure lead (1), with corrosion haloes of red lead oxide (2) and lead carbonate (3) within this ashy aggregate. SEM/EDS analysis on this and other examples confirmed this: red lead oxide, 92.8% Pb (100% PbO); lead carbonate, 86.3% Pb, 5.67% Ca, 7.23% P; surrounding ashes, 43.0% Pb; 10.6%; Ca, 7.83% P (Macphail and Goldberg 2018a)

a number of cave sites, Contrebandiers in Morocco, Roc de Marsal and Pech de l'Azé IV in France, Wonderwerk in South Africa, and Liang Bua in Indonesia, providing significant information about the human and natural environments during occupation (e.g., Goldberg et al. 2018 and Morley et al. 2017).

Open-air occupations are much more prone to reworking compared to caves, but there are some exceptions, for example, and *inundated sites* can show good preservation, although these have to be interpreted with caution. Soil micromorphology has shown that some low-lying terrestrial areas, which were a focus of occupation by hunters and gatherers, for example, were affected by rises in sea level and/or freshwater inundation caused by a similar rise in base level. Together with faunal and artifact refitting analyses, sediment micromorphology showed that butchery and Acheulian hand axe manufacture occurred on mudflats within the intertidal zone at Boxgrove, West Sussex, UK, where a chipping floor was studied within marine alluvium (Macphail and Goldberg 2018a, 186–206). The full 20 km extent of the palaeo-coastline was found through borehole cores and sediment micromorphology analysis of these (Roberts and Pope 2018).

In the case of complex societies, there is the ever-increasing need to identify *archaeological materials*, whether these are of simple constructional origin, such as earth-based daub/adobe, or sophisticated manufactures – for example, lime-based plaster, iron slag, nonferrous metals, alloys, etc. Artisan activity such as soldering lead pipes in Roman and medieval constructions can lead to lead droplets being preserved in occupation sediments (Figs. 3 and 4). In addition, there are other background deposits in the form of fuel and kitchen wastes (charcoal, charred peat, calcitic ashes, bone, burned bone, eggshell) and animal dung and various forms of latrine deposits (Macphail and Goldberg 2018b; Brönnimann et al. 2017a, b). Moreover, the interpretation of *occupation surfaces* within archaeological deposits has been crucial in determining use of space within structures (Gé et al. 1993; Rentzel et al. 2017); this has been further elucidated by experiments (Goldberg and Macphail 2006, 258–263). Such studies have also included ethnoarchaeological investigations as a way of

Archaeological Soil Micromorphology, Fig. 3 Viking Gokstad ship burial mound, Vestfold, Norway; photomicrograph of turf layers ("laminated mull humus"), with vivianite (crystalline iron phosphate [e.g., $Fe_3(PO_4)_2$ H_2O] formed under reduced conditions) associated with humified plant litter layers, and recording migration of phosphate from pasture soil turf within the mound. PPL (Macphail and Goldberg 2018a)

Archaeological Soil Micromorphology, Fig. 4 As Fig. 4, SEM/EDS X-Ray backscatter image of vivianite within laminated mull horizon characterized by layered plant litter and amorphous (humified) organic matter. EDS spectrum found 45.6% Fe (58.7% FeO) and 16.7% P (38.2% P_2O_5). Scale = 1 mm (Macphail and Goldberg 2018a)

understanding *settlement morphology* better (Macphail et al. 2017).

One example is the multi-method geoarchaeological investigation of dung, which included its preservation and spatial distribution associated with cattle management in abandoned Maasai settlements in East Africa (Shahack-Gross 2003). Some Neolithic cave deposits might be totally anthropogenic in origin, as many meter-thick ashed dung and stabling remains were formed by the overwintering of stabled ovicaprids in the Mediterranean region. In the study of settlements and local land use, local building material sources, paths, trackways, cesspits, waterholes and wells, and even cremation, excarnation, and inhumation features require investigation alongside ubiquitous waste disposal midden deposits (Goldberg and Pérez-Juez 2018). For example, at a truncated Viking grave mound at Hesby, Vestfold, Norway, body stains, tentatively identified in the field and subsequently mapped by phosphate analysis (Figs. 5 and 6), were found to be amorphous iron-phosphate-calcium compounds; in the Viking boat grave at Heimdalsjordet wood, iron nails and calcium phosphate-replaced human remains were found (Viklund et al. 2013; Macphail et al. 2013). At both sites standard excavation, geochemical mapping, and soil micromorphology, complemented by EDS, fully characterized this Viking grave mound.

Settlements are often associated with farming communities, and local areas would likely have undergone *clearance* and *cultivation*. One of the earliest contributions of soil micromorphology was its ability to identify cultivation. The microfeatures found in arable soils by Dutch soil scientists allowed workers to tentatively suggest that similar features in disturbed surface soils found under monuments, for example, could record a cultivation history (Romans and Robertson 1983). This suggestion was followed up by experiments in the use of cultivation tools, including replica ards, in France, Germany, and the UK, and the subsequent analysis of the resulting soil microfabrics (see Deák et al. 2017); rice cultivation has also been tackled (Lee et al. 2014). It has always been important, however, to be able to broadly differentiate between the soil disturbance and resulting colluviation caused by cultivation and that caused by woodland clearance (Deák et al. 2017; Macphail and Goldberg 2018a, 290–303). While cultivation tends to homogenize soil, clearance soils, in contrast, might display heterogeneity, with fragments of mixed soil horizon materials being represented. Burned soil might also be present, if fire was involved. Arable soils which are not manured may lose structure

Archaeological Soil Micromorphology, Fig. 5 Map of truncated Viking grave mound (Hesby, Vestfold, Norway); map shows phosphate distribution (dark blue equals highest concentrations – see Fig. 6) (analysis by Johan Linderholm, MAL, University of Umeå, Sweden) (Viklund et al. 2013)

Archaeological Soil Micromorphology, Fig. 6 As Fig. 5, photomicrograph of phosphate-rich area; "body stain" fine silty clay fill inside grave, composed of very abundant iron staining and void hypocoating. Note fibrous secondary iron in voids. Iron also impregnates a relict organic content. EDS found mean 33.8% Fe, max 48.1% Fe; mean 9.34% P, max 14.4% P; mean 2.26% Ca, max 3.77% Ca as mineralized human body residues. PPL (Viklund et al. 2013)

and suffer reduced fertility, and so manuring practices developed. Soil chemistry and field walking may indicate manuring with animal dung and settlement waste. In thin section, the residues from manuring may also be evident. These can be in the form of pottery fragments and burned flint and daub, while coprolitic bone and amorphous phosphate – sometimes embedding calcitic ash – from night soiling, i.e., the use of household latrine waste, may additionally be found.

"Mixed farming" involved both cultivation and animal management, and in some circumstances dung traces can be recognized in ancient arable soils, which are high in organic phosphate of dung origin. In the settlements themselves, use of space investigations can show areas of a long house or a specific roundhouse, for example, which was used to stable animals. In more urban environments, not all animal waste could be used

Archaeological Soil Micromorphology, Fig. 7 Fourteenth-century dumped occupation floor deposits (Pilgrims School, by Winchester Cathedral, Winchester, UK); microprobe map of Context 309B; 309B upper is composed of mixed calcareous (ashy) floor and kitchen waste (Pb [0.06%] enriched); 309B lower is an Fe-stained layered stabling waste dump – which also shows some P enrichment; 1.12% mean Fe, max. 7.12 Fe; 0.162% mean P, max. 1.39% P; 0.394% mean S, max. 1.20% S (see Fig. 8). (Microprobe map of Ca-P-Fe; scale = 5 mm) (Macphail and Goldberg 2018a)

on the fields and was often dumped by roadsides and in open area middens. Interdisciplinary analysis of layered, humified plant-rich stabling waste, employing soil micromorphology, microprobe, macrofossil, and pollen analysis (e.g., at Butser Ancient Farm, Hampshire, UK), has found them to have specific characteristics (Figs. 7 and 8) compared to generally more minerogenic earth floors formed in domestic space (Macphail and Goldberg 2018, 342–377; Rentzel et al. 2017). The latter is likely to include much more kitchen and burned waste and as a consequence often has an enhanced magnetic susceptibility.

Lastly, soil micromorphology has the ability to reveal *site transformation*, when postdepositional processes (Courty et al. 1989, 138–189; Stoops et al. 2018) affect what may once have been recognizable as archaeological stratigraphy. These processes include mechanical working by plants and animals, as well as pedological ones, such as leaching and horizonation. The effect of marine inundation on ancient land surfaces, as noted above, is one example where information on past land use may still be relatively easy to discern. There are other more extreme examples of the transformation of archaeological layers, and these are the Urban Dark Earth of Europe and Amazonian Dark Earths (Arroyo-Kalin 2017; Macphail and Goldberg 2018, 490–515; Nicosia et al. 2017). In the case of northwest Europe, there has been a focus on seeking information on urban land use from dark earth that dates to the late Roman (late Antique) to medieval periods, where homogeneous deposits occur between stratified Roman and Medieval layers. Work in England, France, Belgium, and Italy has shown

Archaeological Soil Micromorphology, Fig. 8 As Fig. 7; stabling waste in Context 309B lower: Overall Context 309 bulk analysis: 34.4% LOI, 3.92 mg g^{-1} phosphate-P, 10.5 × 10^{-8} SI χ, 4.13% χ_{conv}, 736 μg g^{-1} Pb, 84.5 μg g^{-1} Zn, 47.4 μg g^{-1} Cu; Pollen from 309B lower: cereal types (19%) and grasses (57%) and range of herbaceous taxa (21%) are consistent with presence of dung/stabling waste composed of straw/chaff and grass hay; long, horizontally oriented humified monocotyledonous plant fragments, with long articulated phytoliths and intercalated silt. PPL. (Chemical analysis by John Crowther, University of Wales Trinity St David; pollen data from G. M. Cruise, freelance) (Macphail and Goldberg 2018a)

that soil micromorphology is one of the best tools for this kind of investigation, especially when backed up by associated and carefully analyzed small artifact and bulk soil studies that include macro- and microfossil identifications (e.g., pollen and phytoliths) (Devos et al. 2017). Firstly, the decay of earth-based buildings and weathering of lime plasters and mortar, dating to a supposed decrease in urban populations, provide much of the "soil" in dark earth. Secondly, abandoned and robbed-out house plots often became favored areas for ash middening by the remaining town dwellers. Latrine and butchery residue dumping and inhumations in newly formed waste ground within some Roman cities likely reflect a breakdown in municipal regulations. These deposits became almost totally homogenized and weathered into brown soils, ~~for example~~ during second- to third-century AD. Other dark earth layers on the other hand can record a renewed and different use of "urban" space in the late Roman and early medieval periods. Middening and animal dung-rich deposits indicate stock management in a form of rural suburban lifestyle. There is compelling soil evidence that urban space was never totally abandoned in general and that early medieval urban life, recorded by dark earth and the micro-artifacts it contains, was possibly enjoyed by larger populations than during Roman times in some European cities. Numerous case studies in Brussels have allowed the reconstruction of how the settlement developed and changed from early medieval times, for example (Devos et al. 2017).

International Perspectives

It is remarkable to note that the technique of soil micromorphology, first employed across North America and Europe to study questions concerning agronomy and palaeosols, which was first a mainly "European" technique when applied to archaeology, has now gone global. Research and teaching in archaeological soil micromorphology in the North America were almost exclusively carried out by Paul Goldberg at Boston University and his past students. It is surprising that this application has yet to properly catch on in the USA. In Europe, in stark contrast, the subject has gone from strength to strength with major centers of expertise in the UK (Cambridge, London, Reading, Stirling, York), Belgium (e.g., Brussels), France (e.g., INRAP), Germany (Frankfurt and Tübingen), Greece (Athens), Italy (e.g., Milan, Pisa, Padova), Spain (e.g., Barcelona, Lleida, and Tenerife) and Switzerland (e.g., Basel), with other key workers in Czech Republic, Greece, Holland, Romania, etc. Encouragingly, new students of the subject are now emerging from Asia (Seoul, Korea) and North and South America.

Since the 1980s archaeological soil micromorphology has been an integral part of workshops and conferences, within organizations such as the International Union of Soil Science International Working Meetings in Soil Micromorphology (e.g., London 1981, Paris 1985, Austin, USA 1988, Ghent 2001; Lleida, Spain 2012; Mexico City 2016). In addition, since the 1990s, specific archaeological soil micromorphology workshops have been held annually/biannually, to aid training and promulgation of the discipline. In recent

years workshops have also been organized as part of Developing International Geoarchaeology (DIG) meetings, and during 2008–2018 an annual weeklong intensive training course in archaeological soil micromorphology has been organized at the Institute of Archaeology, University College London, where it had all started some six decades previously. Lastly, six workshops and training sessions are taking place across the world in 2019.

Future Directions

Future directions include (1) technical advances and (2) more integrated approaches to site reconstruction. In the first case, interdisciplinary analyses allied to soil micromorphology are correlated bulk analyses for chemistry, magnetic susceptibility, and micro- and macrofossil recovery, paralleled by phytolith, SEM/EDS, micro-FTIR, and microXRF analyses directly on the thin section. The integration of all this data has expanded from use of studies, for example, in houses or caves, to attempts to reconstruct how whole settlements function through time. Such advances permit both the first use of fire and salt working practices to be identified and further allow the modelling of the interconnectivity of activities inside, around, and between settlements – and this also incorporates a landscape functioning as fields, pastures, and routeways for trade.

A

Archaeological Soil Micromorphology Working Group

Richard I. Macphail
Institute of Archaeology, University College London, London, UK

This working group was initiated in 1990 by Richard Macphail at the Institute of Archaeology, University College London (UCL), and with the encouragement of co-workers Marie-Agnès Courty (CNRS, France) and Paul Goldberg (Hebrew University of Jerusalem, Israel; now Emeritus professor at Boston University, USA) (Courty et al. 1989). The first full workshop was organized at Birmingham University (with Susan Limbrey). A pattern developed comprising approximately alternating UK and European venues and organized at Cambridge (C. French, x2), Sheffield (C. de Rouffignac), Stirling (D. Davidson), and UCL (R. Macphail, x3), for example, along with Amersfoort, Netherlands (D. Huisman); Basel, Switzerland (P. Rentzel, x2); Brno, Czech Republic (L. Lisa); Dijon (D. Sordoillet) and Rennes (A. Gebhardt), France; Frankfurt, Germany (H. Thiemeyer); and Poviglio (C. Nicosia and M. Cremaschi), Pisa (G. Boschian, x3), and Milan (L. Trombino), Italy, e.g., Pisa 1998 (Arpin et al. 1998). Since 2014 ad hoc workshops have also been run at UCL in order to coincide with the training course on archaeological soil micromorphology held there. Only one meeting took place in the USA and held at the Boston University field school in New Hampshire (P. Goldberg). This year, 2019, there are workshops in Basel, Brussels, Nancy, and Vancouver.

The meetings are designed specifically to aid students in archaeological soil micromorphology; hence prices are kept low, and the emphasis is on practical help and study. Short presentations are mainly given to introduce material for the workshop and sometimes to improve a study ahead of publication, by getting feedback. In a number of cases, however, workshops have produced publications (electronic Bulletin 1, 1995–1997, Greenwich University web publication edited by Acott, T. and Macphail, R. I.) or have been associated with conference publications, e.g., soils and archaeology (Boschian 2007) and DIG (Developing International Geoarchaeology – Cambridge, 2007) (French 2009). There has also been a close relationship with the International Union of Soil Sciences Commission 1.1 "Soil Morphology and Micromorphology." A joint workshop and conference was held, for instance, at Ghent, Belgium (J. Mikkelsen, R. Langohr and G. Stoops 2001) (Stoops 2003). In 2012, a workshop was held in Spain at Barcelona University (R. Macphail and M. Bergada) in association with the IUSS Soil Micromorphology conference, which was held at Lleida, and where there was a venue for posters and presentations by attendees of the workshop; these were published in Quaternary International (Macphail 2013). In order to test the general competence of students and workers, a few people undertook a self-evaluation test, which showed that an earth science background was generally useful and that a knowledge of background context was essential (Shahack-Gross 2015).

It can also be noted that there have been themed workshops. For example, the link was established between soil micromorphology and (1) soil chemistry (e.g., phosphate and magnetic susceptibility; London 1997), (2) the field (the early human cave site of Tautavel, France 2006; M-A Courty and C. Perrenoud), and (3) phytolith studies in general (e.g., Brussels; Y. Devos and L. Vrydaghs). As training has always been the chief aim of the working group, a short intensive course in archaeological soil micromorphology has also been developed for this need at UCL since 2005. In order to improve identifications and link natural and anthropogenic processes to microfabric and microfacies types, three new textbooks have been published (Karkanas and Goldberg 2018; Macphail and Goldberg 2018; Nicosia and Stoops 2017).

Archaeological Stewardship

Julie Hollowell and Dru McGill
Department of Anthropology, Indiana University, Bloomington, IN, USA

Introduction

Stewardship is a term and concept often invoked in some archaeological circles and entirely absent from others. Archaeologists, anthropologists, museum curators, collectors, government officials, and members of descendent populations have all been considered stewards. Exploring questions about stewardship "for whom?" "of what?" and "to what ends?" reveals that the meanings and applications of archaeological stewardship, though entrenched and bureaucratized in some contexts, are neither universal nor unchanging. In fact, conceptions of stewardship seem to be shifting away from standardized interpretations of management, preservation, and conservation toward more collaborative, inclusive discourses and practices that recognize the special relationships many people have with the past. Collaborative approaches to stewardship sometimes result in restrictions on the activities of archaeologists as they begin to share "the past" on terms other than just their own.

Definition

"Stewardship," as defined by the Oxford English Dictionary (OED Online), refers to the office or duties of a steward (from the Old English, for "house" and "keeper"), which may include caretaking, administration, planning, control, or use of property or resources owned by another. Stewardship is also defined as an ethic, exemplified by responsible planning and management of resources.

In archaeology, stewardship has been closely associated with conservation, curation, anti-looting sentiments, resource management, and the nonrenewable nature of archaeological resources. In *Teaching Archaeology in the 21st Century*, Bender and Smith (2000: 34) present a narrow definition of stewardship as "the wise use of resources [that] can include stabilizing an archaeological site, preserving it in place, excavation, or promoting public understanding of the information content of the resources through site development and interpretation." More generally, and particularly in the context of North American archaeology, the term has come to mean the act of conserving and preserving the nonrenewable archaeological record for future generations, with the aim of promoting knowledge about the past.

Implicit in all of these definitions are assumptions that stewardship is a relationship that denotes responsibility for taking care of something for someone else. Stewardship implies

choosing service over self-interest and, instead, acting in the interest of another. Thus, underlying the discourse of stewardship are various legal, cultural, economic, moral, and political interests, all of which raise fundamental questions of privilege and legitimacy. Who claims to be a steward? For whom? Whose interests does the steward actually serve?

For whom do archaeologists serve as stewards? The concept is fuzzy in this regard. Is it for a universal "everyone" – all of humanity, "the public"– or for "no one" because the archaeological record cannot be "owned?" Or do archaeologists serve the nation-state, which, in many cases, claims legal ownership of archaeological sites and objects? In arguing that archaeological stewardship is performed for "the public," archaeologists remove themselves from the problematic arenas of ownership or culture-based rights and instead purport to act as stewards of, and advocates for, cultural heritage that belongs either to no one, to everyone, or to the state (see Warren 1999).

Historical Background

Historically, at least in western contexts, "stewardship" has never been necessarily egalitarian or altruistic; in fact, the term has often carried an exclusive and elitist connotation. Originally, the term was primarily found in relation to the governance and management of elite wealth and property or as a title for an officer of the state, such as the "Great Steward of England." Later, stewardship was used in commerce to indicate a manager and also as a synonym for servant or aide. The term has long been employed in ecclesiastical contexts, both to refer to the manager of a church's property and the duty to use God's teachings and gifts wisely.

But the concept of stewardship has a much deeper history than the term itself or its co-option by state-based governance systems would suggest. It is deeply rooted in the ethics and practices of land-based peoples throughout time and place. For example, in New Zealand/Aotearoa, the Maori concept of "kaitiakitanga" is closely analogous to "stewardship" but translates more specifically as "guardianship" that is undertaken on behalf of a particular community or *whenua* (J. Coster, e-mail, 23 August 2012).

In recent decades, stewardship has often appeared in reference to the environment and natural resource use. "Earth stewardship" has come to connote one's duties not on behalf of an entity such as god, king, or nation-state but on behalf of the earth and its resilience (see Chapin et al. 2011). Indeed, archaeology should have a great deal to contribute to these discussions (see Hudson et al. 2012).

According to Shawn Malley (2012: 23), the concept of archaeological stewardship emerged in conjunction with excavations of Near Eastern sites by British archaeologists in the mid-1800s, along with the rabid collecting of ancient material culture by western museums. Malley (2008: 623) notes that "the paternalistic ideology of Western stewardship" that pervaded British archaeology at the time served to rationalize less benevolent, imperialistic interests. By the late 1880s, western museums promoted themselves as stewards of the past for the public, responsible for educating the masses and promoting national identity. These deliberate policies reinforced particular ideologies and public imaginings about archaeology that later coalesced under the heading of "stewardship" (see Smith 2004: 85).

In the early 1900s in the United States, just as natural resource conservation movements were on the rise and the discipline of archaeology was beginning to embrace more systematic methods of research and training, massive commercial excavations of noteworthy sites by private entities prompted government action. The 1906 Antiquities Act essentially appointed archaeologists as protectors and stewards of sites on public lands, acting in the national interest. In the decades that followed, the US government funded many large excavations – whether to salvage the remains of earlier cultures, to investigate the "Mound builder" myth, or to bolster the American economy. Other nations also recognized the power of archaeology to reinforce nationalist narratives and developed similar programs. This use of government funds for archaeology endowed the notion

of stewardship with a sense of public accountability that remains prominent today.

Laurajane Smith (2004: 84–92) associates the development of the concept of archaeological stewardship with the growth of liberalism – the idea that governments think they know what is best for others. She points out that long before the term actually came into use, archaeologists had assumed stewardship of the histories and prehistories of others. This presumption was nurtured by early twentieth century ideas that cultural objects embodied past identities in ways that revealed themselves through scholarly study. Subsequent ideological positions within archaeology, including the claim of processual archaeology to be a science of human behavior, the development of heritage as a public education issue, the establishment of CRM archaeology as a profession accountable to public and private interests, and the articulation of a "conservation ethic," all lent support to a notion of archaeological stewardship.

In the 1960s and 1970s, the United States, Great Britain, and Australia were among nations that enacted archaeological resource management legislation. This was in part a reaction to increased development, land use changes, and other threats to archaeological sites. Many of these acts defined the proper care and management of heritage objects and sites in terms of "preservation" or "stewardship." In many instances, sacred sites or other places of heritage value and their contents were reinscribed as "archaeological resources," in need of protection by trained professionals. The implementation of these top-down policies quickly fell to university-trained archaeologists, creating a cadre of professional managers that assumed both a legal right and a moral responsibility to serve as guardians of sites and objects.

By the mid-1990s, "stewardship" had been adopted as the primary principle of ethics by the Society for American Archaeology (SAA) (Lynott and Wylie 1995). This signaled an expanded responsibility for archaeologists, far beyond merely doing "good science." The concept of stewardship spoke to many pressing issues of the time, such as the growing reluctance to excavate except at threatened sites, the "curation crisis," threats posed by looting and the antiquities market, the need to preserve archaeological records, and a mandate for public outreach. Most of the other Principles of Archaeological Ethics set forth by the SAA evolved to address what stewardship meant in various contexts. Clearly, stewarding the archaeological record "in the public trust" entailed serving many different – and sometimes conflicting – interests.

During the 1980s and 1990s, archaeologists faced ardent criticism from Aboriginal peoples, especially in regard to assumptions about the right to study Aboriginal pasts and claims of ownership by nation-states over heritage sites and objects. Reframing these potentially messy issues in terms of stewardship, instead of rights or ownership, could be called a strategic move on the part of state-based agencies, since it "require[d] all sides to accept their responsibilities as stewards and to put aside professional and political interests in order to act in the best interest of the property and the cultural heritage that property represents" (Hanna 1993).

But is it possible to put aside professional and political interests? What does it mean to act in the best interest of the archaeological record or the heritage it represents? Could the use of the term stewardship in such contexts – intentionally or unintentionally – serve to depoliticize archaeology and neatly smooth over or mask more contentious issues of rights and sovereignty? (see Smith 2004, Chap. 5).

Current Contexts

How is the term "stewardship" being used in various heritage- and archaeology-related contexts today? The brief discussion below incorporates responses to a query posted on the World Archaeological Congress listserv.

Government

The normative force of the concept of stewardship is clear from how pervasive and embedded the term has become in "official" discourses, where it puts a benevolent spin on who has the authority and expert knowledge to make decisions about how to manage, for whom, and to what ends. Federal programs typically follow standardized legal definitions that equate archaeological

stewardship with cultural resource protection, preservation, management, and public outreach, performed under the direction of trained professionals. In many government contexts, "heritage stewardship" has become synonymous with "heritage management." Stewardship is also a central tenet of numerous government-sponsored public education programs, which impart particular values to citizens through participatory archaeology projects and "site steward" programs.

Sometimes codified definitions of stewardship embedded in agency policies and regulations conflict with ideas about good stewardship in practice. For example, US regulations legally mandate indefinite or perpetual curation of federally accessioned archaeological collections (see 36 CFR 79). This severely limits what actions can be taken, even when repatriation, reburial, or disposal is more appropriate.

Private Sector

Today the majority of archaeological work is conducted by private sector cultural resource management firms (CRM; also known as archaeological heritage management or AHM). In this context, stewardship typically refers to practices and decisions that protect or increase the significance and value of heritage resources. Here, preservation and conservation often compete with economic development, and stewardship may involve calculated destruction or mitigation that attempts to balance economic, private, and state interests. Some heritage management companies invoke "stewardship" as an advertising strategy, to express their moral superiority in contrast to other firms that practice "mere compliance."

The recent growth of private sector involvement in historic preservation has spawned a drove of "heritage stewardship" consultants who seek to bridge private interests and government mandates. Many of these consultants talk about heritage as an asset or form of capital and good stewardship as the means of protecting and growing these investments.

Professional Contexts

"Stewardship" appears in the codes of ethics and professional statements of many archaeological societies and not at all in others. For example, the Archaeological Institute of America's Code of Professional Standards describes archaeologists as "primary stewards of the archaeological record," while the professional statements of the Council for British Archaeology mention stewardship only briefly, in connection with local sites, and the Australian Archaeological Association makes no reference to "stewardship." The SAA Principles of Archaeological Ethics, which declare "stewardship" as the primary principle, are widely cited in archaeological literature and training and have been adapted or adopted by a number of other national archaeological organizations, including the Society of Philippine Archaeologists and New Zealand Archaeological Association.

A refreshing approach is found in the Canadian Archaeological Association's (CAA) Principles of Ethical Conduct, ratified in 1996. As in the USA and New Zealand, the CAA lists "stewardship" as its primary principle but defines it as "respect for archaeological remains and for those who share an interest in these irreplaceable and nonrenewable resources now and in the future." This is notable for its openly stated inclusion of other interested persons. The CAA also has a Statement of Principles for Ethical Conduct Pertaining to Aboriginal Peoples, which essentially recognizes Aboriginal stewardship as a right.

Using examples of high-profile repatriations in the USA (Kennewick Man) and Australia (Lady Mungo), Claire Smith and Heather Burke (2003) have illustrated how differing interpretations of stewardship deeply affect the professional practices and outcomes of archaeology. They point out that a code of ethics which cites stewardship of the archaeological record as its primary ethical principle invokes a very different epistemological standpoint and set of practices compared to a code that foregrounds people and relationships (as do the CAA and the World Archaeological Congress).

Museums also take their professional role as stewards very seriously. During the twentieth century, most museum professionals came to see themselves as stewards not simply for the

nation-state but with a mandate to serve the public. In yet another transformation of their stewardship role, a growing number of museums today act as caretakers of objects for particular descendant and source communities. This has opened up the concept of archaeological stewardship to new relationships and practices. It can also mean that archaeologists and other researchers may encounter restrictions on access to particular objects or cultural information, unless appropriate permissions are obtained.

University Contexts

The term "stewardship" is noticeably absent from most introductory archaeology texts. When it does appear, it generally occurs within discussions of CRM or Public Archaeology. As Sonya Atalay advocates (2008: 139), archaeology courses should be studying the social, political, and historical conditions that have led archaeologists to claim to be stewards of the archaeological record in the first place. University-level archaeology programs with a focus on stewardship have tended to be located in North America, and they are typically geared toward training in heritage management. This is changing, however gradually (see "Future Directions" below).

Indigenous Uses of Stewardship

When Indigenous peoples – who have their own potent relationships, values, and forms of knowledge associated with ancestral sites and objects – talk about stewardship, it can mean something quite different from what most archaeologists take the term to mean. According to Navajo archaeologist Rena Martin (1997), all members of the Navajo community consider themselves stewards of the land and what it offers, and archaeologists are often viewed as interlopers who disturb the dead and their belongings.

Many descendant or source communities recognize stewardship as describing the relationship that Indigenous populations had with their lands and cultural resources prior to European colonization, a relationship that many are seeking to recover (Atalay 2008: 123). They are concerned that their heritage continues to be appropriated without their involvement or consent, and they see this as a serious violation of their own principles and responsibilities as stewards.

Some First Nations and other Indigenous peoples utilize the term in governance to express their rights and responsibilities to protect and nurture cultural resources. For example, in 1988 the Navajo Nation passed a Cultural Resources Protection Act (CMY 19–88, 1988) based on the concept of stewardship. The Act suggests the same end goal described by archaeologists (to benefit present and future generations) but goes further in advocating collaboration among all parties who play a part in administering Navajo cultural resources. As a result of amendments to the US National Historic Preservation Act in 1992, over 100 federally recognized tribes have established Historic Preservation Offices to administer duties that would otherwise fall under state supervision. Meanwhile, Indigenous archaeology, which integrates tribal-based teachings with principles of "cultural heritage stewardship," has become a vibrant subfield within archaeology (see the entry on "▶ Indigenous Archaeologies in Archaeological Theory" by George Nicholas and Joe Watkins).

Key Issues

In many ways, the concept of stewardship has acted to promote the idea that archaeologists have a special, or even primary, relationship to "the past," one that overrides the interests and relationships of others. What rationales have been used to justify this presumption of privilege?

- The training archaeologists receive does indeed give them a special relationship to "the archaeological record" (a term that claims the past as the domain of archaeologists) and implies that this domain is best cared for or managed by trained professionals (see Hamilakis 2003).
- Government-mandated policies that designate archaeologists as managers and protectors of heritage resources.
- The discourse of professionalism and expertise, which distances archaeologists from the

public and at the same time creates a sense that experts are needed to help people understand and care for the past (see Zimmerman 2000).
- The "implicit presumption of scientific privilege," justified by intellectual and scientific authority (see Wylie 1996).
- The "fiction of universalism" that supposes a transcendent, panhuman interest in scientific knowledge about the past (Wylie 2005: 61–2).
- Related to this, the notion that archaeologists, in their role as stewards, are acting as "impartial caretakers of a common heritage" (Bendremer and Thomas 2008: 62).

Over the past 30 years, each of these presumptions has been deeply criticized and challenged by archaeologists, Native peoples, and others (see McGuire 1992; Wylie 1996, 2005; Zimmerman 2000; Groarcke and Warrick 2006; Bendremer and Thomas 2008).

At the turn of the century, David Lowenthal (2000: 19) declared that heritage stewardship had become an "enterprise of technical expertise, while the general public, devoid of professional competence, stands aside." He repeatedly warned against this kind of exclusivity, insisting that effective stewardship requires engagement with the complications of everyday life. Alison Wylie (1996, 2005) has long argued that archaeological expertise should not override other interests or ways of connecting with the past. Leo Groarcke and Gary Warrick (2006) find the claim that archaeologists are acting for "all of humanity" problematic and impossible in practice, as if "the public" were a homogenous entity with interests synonymous with those of the state. Cornelius Holtorf has pointed out that, insofar as stewardship claims to preserve or protect on behalf of future generations, there has been no substantive discussion about what future that should be or why we should assume that the heritage being preserved now will be valued then.

John Carman (2005: 75–6) has gone so far as to call the concept of stewardship a justification employed to legitimate state claims of cultural property ownership. Laurajane Smith (2004) has exposed stewardship as a strategy for government control and authority that positions archaeology to mediate between the record of humanity's past and interest groups in the present. She argues that archaeological stewardship is often an appropriation of someone else's history in disguise, used to justify "pastoral care" and legitimate archaeological intervention (Smith 2004: 100). Nick Shepherd and Alejandro Haber (2011: 13) have discussed how the concept of archaeological stewardship acts to devalue and transform local knowledge and ways of interacting with sites and objects into a global, professionalized discourse of "heritage" and "resources" in ways that enable nationalistic interventions or re-inscriptions of local histories.

In spite of their robust nature, these and other critiques have not led to a reenvisioning of stewardship among the majority of practicing archaeologists. Nevertheless, there are archaeologists and Indigenous community members alike who are giving serious thought to what it means to be a good, active steward and to identifying qualities that characterize leadership in heritage stewardship (see, e.g., Welch et al. 2011). All in all, although some people advocate doing away with the term altogether, there are also important ways that the concept of archaeological stewardship is being redefined, expanded upon, and recast.

International Perspectives

The term "stewardship" may be an entrenched part of the discourse of heritage in North America, but in global heritage contexts and in many places around the world, its use is much more uneven, though the underlying rhetoric of preservation, protection, or conservation "in the public trust" is usually present. With a few exceptions, stewardship is noticeably absent from international discourses on heritage. UNESCO's mandate includes "promot[ing] the stewardship of the world's cultural resources, including the built heritage, which constitutes our collective cultural memory," but with no discussion of what this means. The International Council of Museums (ICOM) defines stewardship in its code of ethics

in relation to a museum's duty to hold collections "in the public trust":

> Collections are a significant public inheritance. . .inherent in this public trust is the notion of stewardship that includes rightful ownership, permanence, documentation, accessibility, and responsible disposal. (ICOM 2004)

Responses to a query posted on the World Archaeological Congress listserv indicate that stewardship is not a term commonly employed in archaeology outside of North America. In fact, many felt that it had negative connotations, related to an imbalance of power over decisions about the care and management of heritage, in favor of national governments and archaeologists.

In South America, the term "stewardship" is also not commonly used. A word that sometimes takes its place is "fideicomiso," which refers to holding property in trust but also connotes a process of appropriation and disenfranchisement that is tacitly normalized by the state (Herrera in press).

A notable exception is the ICOMOS New Zealand Charter for the Conservation of Places of Cultural Heritage Value, which recognizes the Maori concept of "kaitiakitanga" as an obligation that extends beyond legal ownership (ICOMOS New Zealand 2010: §3). Although the text of the Charter does not mention stewardship, the glossary defines "kaitiakitanga" as ". . .the duty of customary trusteeship, *stewardship*, guardianship, and protection of land, resources, or taonga [cultural treasures]."

A few international colleagues saw value in using the term – not, however, to define an archaeologist's rights or responsibilities but rather when characterizing a community's right to manage resources on local terms. Several respondents noted that, in many international and intercultural contexts, and outside of North American governance circles, stewardship was more commonly associated with land and landscapes instead of sites and objects, and as an alternative to ownership. In this sense, the responsibilities of archaeologists may actually fall under the broader duties of land stewardship.

Future Directions

A number of significant changes in archaeology in recent years have challenged normative conceptions of stewardship and have brought about shifts in its meaning and uses. These include:

- Acknowledgment that living people(s) have potent interests in and intimate relationships with the past and may be strongly affected by the actions and interpretations of archaeologists
- Shifts in authority – in who is working for whom and who sets the agenda
- Respect for alternative, culturally appropriate ways of conserving, curating, and caring for sites, objects, and cultural knowledge
- Realization that the imagined divide between cultural knowledge and "science" is false as well as disrespectful of the diverse ways that people value the past
- Greater degrees of collaboration among those who have special relationships with "the archaeological record" or who are otherwise affected by archaeology
- In particular, the inclusion of non-archaeological voices and values in planning, interpretation, and decision-making

These changes have helped generate new conceptions of "stewardship" that begin to move beyond privileging archaeological knowledge or expertise.

Below are some examples of how "stewardship" is taking on new meaning in archaeology and heritage-related research and practice.

Shared Stewardship

Shared stewardship has become an important concept in international negotiations regarding ownership of antiquities and cultural property, where questions of valid title are so difficult to resolve (see Lyons 2002: 133). In another context, the US National Park Service now references "shared stewardship" as one of its "core values," purportedly as a way to signal a commitment to collaborating with members of the global preservation community. Shared stewardship is also occurring

with greater frequency on small, local scales, where it means sharing control, authority, management, and/or decision-making. Examples include repatriations to source communities, the co-management of heritage sites, development of memoranda of understanding between museums and cultural descendants, and the use of culturally appropriate curation practices.

Collaborative Stewardship

Collaborative stewardship moves even further toward inclusiveness, honoring and supporting the obligations, values, and alternative approaches of others, and thus directly challenging archaeological privilege. For many archaeologists, incorporating alternative conceptions of stewardship, worked out in collaboration with others, is an important way to decolonize archaeology (see Nicholas 2005; Atalay 2008, 2010).

Community-Based Stewardship

Community-based stewardship – which is essentially collaborative stewardship guided by community-identified needs – is becoming an important aspect of twenty-first century archaeological practice. In community-based projects, archaeologists may act as facilitators, promoters, educators, or benefactors, while local people are full partners and beneficiaries. Frequently the role of steward, over time, is "devolved" from archaeologists or the state to those living and working in the area. The museum at Agua Blanca, Ecuador, is one example where, after years of collaborating with archaeologists, the stewardship of local sites and management of the local cultural center/museum is today in the hands of local townspeople (see McEwan et al. 2006).

Community-based stewardship presents archaeologists with considerable challenges, since community needs may have more to do with securing economic opportunities, jobs, or funding for local projects than with conventional archaeological goals. Swedish archaeologist Eva Svensson (e-mail, 28 October 2011) suggests that since heritage has become such an important asset for development, a community-based conception of stewardship could lend weight to citizen and community voices and thus help balance development decisions (often made by outsiders) with ideas about heritage and its significance held by local people.

Knowledge Stewardship

For archaeologists, knowledge stewardship has long been an important aspect of their own professional practice, but today it also refers to respect for how others have their own, sometimes very different, methods of caring for, nurturing, and sharing knowledge and other intangible aspects of culture. Atalay (2010: 65) notes that "[i]n many cases, caring for knowledge and place simultaneously was often interwoven in traditional forms of stewardship." For example, the Ojibwe concept of *gikinawaabi* encompasses the responsibility of elders to protect and pass on knowledge. In this and many other instances, archaeologists are also learning that good stewardship sometimes means respecting restrictions on access to or circulation of cultural information or knowledge.

Indigenous Heritage Stewardship

Indigenous heritage stewardship is a term being used to describe approaches developed by, for, and with Indigenous communities, which place archaeology in the service of Indigenous goals and principles and have social justice as an underlying core value.

For example, for the White Mountain Apache, archaeology and heritage stewardship are playing an important role in ongoing efforts to strengthen tribal sovereignty (Welch et al. 2006). The tribe has created heritage policies founded on Apache principles of stewardship, which extend to caring for sites and objects that, due to historical circumstances, lie outside current tribal boundaries and ownership. These policies in turn inform tribal law, governance, and economic development decisions. Similarly, the Hul'qumi'num Treaty Group of Vancouver Island (Canada) has articulated protocols based on their own conceptions of heritage law to guide decisions about land and resource development (see McLay et al. 2008).

Today, several universities, including Northern Arizona University (USA) and University of

Victoria (BC) Canada, offer programs in Indigenous Heritage Management (see Hunter 2008). John Welch, who teaches Indigenous Heritage Stewardship at Simon Fraser University in British Columbia, believes that this is the direction that the concept of stewardship is heading within archaeology.

Deliberative Democracy

When the participants of a 2008 conference session on "The Ethics of Archaeological Stewardship" shared their experiences, they discovered that "stewardship" had a different meaning in each and every situation (Shoup and Monteiro 2008). What seemed to matter most was the attitude of the archaeologist – in particular, an attitude of respect, the ability to listen, and a willingness to integrate local needs and interests into the research agenda. The concept of "deliberative democracy" emerged as a term that encompassed the kinds of practices that archaeological stewardship should nurture, both in daily interactions, dialogues, and decisions with local people and in broader heritage contexts (Shoup and Monteiro 2008: 331).

These are just a few examples of ways the concept of stewardship is being revisioned in archaeology.

Conclusions

The idea that stewardship is the purview and privilege of archaeologists and other heritage specialists is still very entrenched – especially in government agencies, international bodies, and private sector heritage industry. In some places, use of the term in relation to archaeology is virtually nonexistent. In others, it marks deliberate movements toward self-determination and more equitable practice, signaling empowerment of local people and descendant communities to manage, protect, and make decisions about heritage and its uses.

In general, the meaning of stewardship in archaeology has shifted over the past generation from being almost exclusively object-centered to becoming more relationship-centered and from being defined by state-based policies or universalisms to recognizing pluralisms and particularisms that embrace more collaborative and inclusive approaches. Archaeologists may find that these new approaches and relationships mean additional restrictions on current disciplinary practices as they find ways to share their sense of duty to the archaeological record with others. Whatever the case, as part of understanding and confronting the foundation of their discipline and its practices, archaeologists must continue to revisit the questions: stewardship – of what? for whom? on what terms? and to what ends?

Archaeological Theory: Paradigm Shift

Ewa Domańska[1] and Monika Stobiecka[2]
[1]Adam Mickiewicz University in Poznań, Poznań, Poland
[2]University of Warsaw, Warsaw, Poland

The humanities and social sciences have undergone major changes in the past two decades as a result of (1) the critique of anthropocentrism, Eurocentrism, and secularism; (2) the development of new connections between the humanities and the natural sciences, especially the life and Earth sciences; (3) the conventionalization of the interpretivist-constructivist paradigm which has prevailed in the humanities since the 1970s; (4) the emergence of various, often conflicting, trends related to new materialism, new empiricism, new animism, and new vitalism that share a turn away from the text and a return to materiality that is present and accessible in the "here and now"; (5) the digital turn and technological developments that transform the tools and methods available to researchers; and (6) the opposition to the prevailing "fast" mode of academic work with the rise of "slow science." This shift has been prefigured by the development of global capitalism, post-capitalism, or neo-capitalism, the crisis of liberal democracy, migrations, terrorism, new cases of mass killings, climate change, the ecological crisis, natural disasters, and broadly understood technological progress (biotechnology, computer sciences, robotics, artificial intelligence) – phenomena which the humanities and social sciences have attempted to describe and comprehend. The alternative trends proposed by scholars who represent cutting-edge research perspectives and lead the way in disciplinary debates suggest a need to thoroughly rethink our notions of life, what it means to be human, and the relations between the human and the nonhuman, and humans and technology, while also finding ways to break away from the Western tradition of anthropocentrism with its reductionist concept of matter as empty, lifeless, and lacking agency.

The variety of research tendencies and approaches constituting the contemporary human and social sciences cannot be subsumed under homogeneous paradigms (understood here after Thomas Kuhn as research models or as a disciplinary matrix). Nevertheless, in order to present a simplified model of the paradigm shift which has arisen in the humanities and social sciences in recent decades, two dominant models might be identified: (1) the interpretivist-constructivist (postmodernist) and (2) the non- or post-anthropocentric, which is associated with other aspects of the shift toward non- or post-Western, post-global (planetary/cosmic), and post-secular approaches (ecological, the posthumanist). This shift can be observed, for example, in the recent interest in animals, plants, and things. However, while they are treated as interesting research topics and examined by means of known theories, quite often researchers hesitate to address the relationship between humans and nonhumans in the context of the radical avant-garde tendencies represented by such scholars as Karen Barad, Jane Bennett, Rosi Braidotti, Dipesh Chakrabarty, Donna Haraway, N. Katherine Hayles, Tim Ingold, Bruno Latour, Anna Tsing, Eduardo Viveiros de Castro, and Cary Wolfe, as well as artists including Eduardo Kac or Stelarc, even though artists often anticipate the appearance of new facts.

From the perspectives of these avant-garde tendencies, the concept of a global world appears increasingly reductive, while planetary identification backed by the ideas of transculturalism looks to be of growing interest (Spivak 2003; Keller 2018). Explorations of human subjects deprived of personhood (dehumanized prisoners of camps, the stateless, those enmeshed in extreme poverty), those who have transcended humanity thanks to biotechnological progress (disabled persons given special abilities thanks to prostheses and transplants) and the non-dead (the corpses and, in popular culture, zombies and vampires), offer particularly interesting perspectives. The non-human has become the paradigmatic figure of the contemporary and a guidepost to the future.

Scholars are increasingly interested in "disobedient" subjects, who often require complementary approaches combining the human, social, and natural sciences, such as environmental studies, animal studies, plant studies, as well as elements drawn from "art and science" and from science and technology studies (STS). A major shortcoming of today's human and social sciences is that the theories used lead to research findings that are incommensurable with rapidly changing realities and social expectations. That is to say that although scholars observe ongoing changes and write about them, creating new research areas in the process, they ultimately lack the tools to conceptualize these changes.

The interpretivist-constructivist paradigm was never a homogeneous whole but a set of various research approaches and perspectives which have evolved in time and space. This paradigm might be regarded as characteristic of the so-called new humanities, which includes a variety of interdisciplinary trends such as gender and queer studies, postcolonial studies, ethnic studies, and disability studies, among others (Fuery and Mansfield 1997). The interpretivist-constructivist paradigm has played an interventionist, emancipatory, and even insurrectionary role, actively participating in social change. Throughout its dominant period in the humanities, scholarship has become a form of political activism that has focused its interest on such key concepts as identity, power, and others. The characteristics of this paradigm include a pragmatic approach to research, its politicization, emphasis on the relations between knowledge and power, the ideological engagement of the researcher who wants to participate in social change, and the struggle for justice, unmasking the practices of power, belief in the construction of social reality, and focus on reclaiming forgotten and/or excluded pasts. In terms of epistemology, the interpretivist-constructivist paradigm has promoted interdisciplinary approaches and epistemological eclecticism, the theory of the situated subject of knowledge (i.e., its subjectivity), and reflexivity, thus emphasizing the pertinence of interpretation over an interest in truth.

After the long period of dominance of postmodern "weak science," together with its politicization and ideologization, the scholarship which is at the avant-garde of the paradigm shift is beginning to look for ways to reestablish its authority, for new goals and standards, and for solid knowledge based on evidence and affording a sense of security in the world. It begins to readdress such classic worldly issues as good and evil, truth, values and virtues, universals, human nature, religion, and the sacred while looking for practical wisdom that would help answer the question of how to live together in conflicts.

The limitations of the interpretivist-constructivist paradigm are evident in relation to the process that sociologist of science Andrew Pickering described as the "posthumanist displacement of our interpretative frameworks" (Pickering 1999: 561). One manifestation of this process is the emergence of the posthumanities (Badmington 2007), defined as a set of tendencies and research trends related to the intellectual movement and ethical stance known as posthumanism (Badmington 2000; Wolfe 2010; Braidotti 2013). They construct knowledge that critiques and/or rejects the human's central position in the world, hence their preference for non-, anti-, or post-anthropocentric approaches (ideas related to a non-anthropocentric paradigm appeared as early as the 1990s). In a sense, the posthumanities can be thought of as non-anthropocentric humanities, although this definition is too paradoxical to be embraced without

reservations. The primary research interests of the posthumanities include the boundaries of species identity, relations between the human and the nonhuman (the human's relations with technology, the environment, animals, things), questions of biopower, biopolitics, and biotechnology, and technology's impact on the contemporary world. The point is not to exclude the human from scholarship but to critique the view that presents the human as the master and center of the universe.

Environmental history scholars have long criticized cultural and social determinism and the Euro- and anthropocentric character of knowledge. Richard C. Foltz has emphasized the need to depart from fragmented knowledge and instead replace it with an integrated vision of the relations between humans and nonhumans and to reframe the concept of agency as the historical (non-intentional) agency of nonhuman actors. He observes that "the environmental crisis is the playing field on which all other issues meet," while "climate change may well turn out to be the historical event of our times, which future historians may see as the matrix within which all other historical events of our era unfold" (Foltz 2003: 20).

This kind of thinking has inspired the ideas popularized by Fritjof Capra in the late 1990s. Capra argued that we were witnessing a paradigm turn in science away from physics and toward biological sciences accompanied by a change of values as researchers embraced the principles of ecological thinking (Capra 1997). During recent decades, there has been an observable shift from the interpretivist-constructivist paradigm toward the posthumanist paradigm (working label) that includes various pro-environmental approaches. Richard McNeil Douglas argues that "Environmentalism itself is not the paradigm, rather its antithesis, erupting from the growing contradiction between progress and reality, which tells us that a new paradigm is needed" (Douglas 2010: 214). However, posthumanities and ecological or environmental humanities, with their non-anthropocentric approach (seeing the world in terms of collectives of humans and nonhumans, companion species, and kincentricity with the natural world) and interest in traditional ecological knowledges, are already indicators of a growing fundamental change in scholars' consciousness. Recently, Bruno Latour and Timothy M. Lenton announced that we are witnessing not only a paradigm shift in various fields of knowledge but "a shift in worldview," meaning a major change in the "distribution of traits affecting science as well as politics, morality, and the arts" (Latour and Lenton 2019: 661).

Processes of "indigenizing the academy" – as Devon Milhesuah and Angela Wilson have called it (Milhesuah and Wilson 2004) or further processes of decolonization (Rizvi 2006) – are worth mentioning here; they argue – as do postcolonial scholars – that the academy needs an alternative to the European tradition of thinking since this tradition does not offer a worldview that will provide a successful survival tool. In a sense, the paradigm shift discussed here marks a return to the evolutionary understanding of scholarship as adjusting to a changing reality and a resumption of the debates about whether scholarship (the humanities and social sciences) has any survival value for the human species and for life in general (Hodder 2018). This shift is interesting and important because it adopts new points of reference and new goals for the production of knowledge. One of its reference points is life itself or *zoe*.

The changes described above provide a context for the growth of "thing studies" (part of the so-called new material culture studies) which is also associated with an interest in the new materialism that manifests a departure from the traditional (Cartesian) concept of matter as passive and lifeless (Cole and Frost 2010). Characterized by focus on technological progress and humans' growing dependence on things, validation of indigenous cultures' view of the relations between humans and things, and reliance on quantum physics, new materialism proposes a thorough rethinking of the concepts of matter, vitalism, and animism in the completely new context of today's world (Lury et al. 2006; Harvey 2006). Matter and things become active, unpredictable forms of constant becoming with non-intentional agency (Knappett and Malafouris 2008; Bennett 2010; Lury et al. 2006).

While observing a growing interest in thing studies as well as in animal studies and plant studies, it seems that the reference point for human and social sciences is increasingly shifting from the human being and the humanist, anthropocentric view of its dominant position in the world to the human being as a species (Chakrabarty 2015), considered in the context of the so-called deep or big history of life on earth (Christian 2004; Smail 2008) and understood as one life form among many. Paradoxically, in the current geological epoch referred to as the Anthropocene (Solli et al. 2011; Edgeworth et al. 2014), which is characterized by the massive human impact on the environment and the climate, today's human and social sciences are defined by debates involving a critique of anthropocentrism, posthumanism, species identity, and interspecies relations (Edgeworth et al. 2014).

One sign of the major reconfigurations in the theory of the human and social sciences is the shift of research perspective from the vertical to the horizontal. Generally speaking, the vertical model of knowledge is being replaced by the horizontal model as the so-called flat alternatives and/or relational approaches grow in importance. Indeed, it is legitimate to say that contemporary human and social sciences are all about relations and interconnectedness. Among the many factors stimulating this shift are quantum physics, genetics and technology studies, as well as traditional ecological knowledge (Descola 2013), which all share the conviction that all things are connected (cf. Hodder 2018). However, Raymond Pierotti and Daniel Wildcat indicate, as suggested above, that connectivity "is not simply a homily and a romanticized cliche, but instead is a realization that no single organism can exist without the web of other life forms that surround it and make its existence possible" (Pierotti and Wildcat 2000: 1336). The pyramidal metaphor of viewing reality has given way to the metaphor of entangled relations, with webs, nets, and networks, as well as assemblages, collectives, kinships, companions, and communities, crucial (Hodder 2012; Watts 2013).

Thus, this shift is a result, firstly, of ecological thinking, which endorses an ontology of connectivity between humans and nonhumans and humans and the environment, and, secondly, of science and technology studies, which examine the relations between humans and things (Hodder 2018). It has resulted in a widespread use of flat ontologies and relational approaches. Flat alternatives operate in terms of horizontal relations, associations, assemblages, symbiotic communities, emergence, and entanglement. Examples of such flat ontologies are Bruno Latour's actor-network theory (Latour 2005), Manuel DeLanda's assemblage theory (DeLanda 2006), Ian Hodder's concept of entanglement (Hodder 2012, 2018), and Christopher Watts' relational archaeology (Watts 2013). They share a critical approach to traditional social constructivism, whose idea of society as socially constructed establishes a certain social determinism (sociocentrism) focused on human subjects. Many scholars agree with Latour, who argues that society is not constructed exclusively by humans but emerges as a result of human-nonhuman interactions. In such approaches, the idea of hierarchy is being replaced by that of symmetry.

The idea of symmetry has become so widespread in the human and social sciences that avant-garde archaeologists, following in Latour's footsteps, have formulated the project of "symmetrical archaeology" (Witmore 2007). In his *In Defense of Things*, Bjørnar Olsen presents an egalitarian approach and a more symmetrical view of reality. He assumes that things, and material culture in general, are beings that coexist with other beings like humans, animals, or plants. They all have material properties and share the world they inhabit. Symmetry in this context does not mean that all these beings are equal or the same; they are seen as different and diversified forms of being, but the differences among them should not be framed as ontological dualisms or negations. Rather, they are nonoppositional, relative differences that foster collaboration, transmission, and exchange (Olsen 2010; cf. Watts 2013). Olsen's project encouraged researchers to refer to a variety of new materialisms (Bennett 2010), speculative realism (Bryant et al. 2011) or agential realism (Barad 2007), which is particularly visible in the theoretical discussions (Witmore 2014; Hodder

2018). Material culture studies, the "material turn" and the "(re)turn to things," and object-oriented approaches together with new materialisms mark the broad horizon of the materialistic paradigm shaping archaeology today.

Another paradigm that relates to humanities and social sciences' recent interest in natural sciences is the "scientific turn," which also features in discussions as Processualism 2.0. It is evident in a growing body of scholarship on archaeometry, also termed archaeological science. Its progress is strongly influenced by research on ancient DNA and epigenetics (Templeton 2019), stable isotope analyses, lipid analyses, chemometrics, and thermal analyses. Results of physical and chemical analyses provide more holistic insight into relations between humans, nonhumans, and past environments.

The "scientific turn" benefits also from the "digital turn." The popularity of big data, the development of databases, and the variety of digital, virtual, and cyber methods have deeply transformed archaeological research (i.e., Forte 2010). A growing body of literature reveals the polarization surrounding digital, virtual, and cyber tools, often emphasizing its undertheorization (Huvila and Huggett 2018) while on the other hand pointing to the epistemic possibilities enabled by databases and big data (Kintigh et al. 2014).

The "scientific turn" and the "digital turn" allow archaeology to address the Grand Challenges (Kintigh et al. 2014) and draw big pictures. Those ambitions are currently criticized as embodiments of "fast science" relating to neo-capitalist modes of scientific production (Cunningham and MacEachern 2016). Clear opposition to "big science" is now articulated by proponents of "slow science" or "slow archaeology" (Rizvi 2006; Cunningham and MacEachern 2016). "Slow archaeology" is often supported by a variety of public archaeologies, including community or indigenous archaeology. This branch of archaeology is mostly concerned with social well-being and the significance of archaeology for global and local communities.

Archaeology likewise addresses the needs of the contemporary society by engaging with the more recent past (Buchli et al. 2006; Harrison and Schofield 2010; Sturdy Colls 2016; González-Ruibal 2019), complementing research conducted within the fields of history, cultural anthropology, human geography, and cultural and social studies. Future-oriented perspectives might be found in archaeology's recent interest in the Anthropocene. Matthew Edgeworth represents archaeologists within the Anthropocene Working Group. Archaeologists discuss the golden spike (the date when the Anthropocene started), heritage in the Anthropocene, and future-oriented practices (Solli et al. 2011; Edgeworth et al. 2014; Bauer and Bhan 2018).

The future of the humanities and social sciences is inseparably connected with reflection on the future of the Earth, the human species, trans-speciation, and life itself. Thus, knowledge about the past increasingly becomes a future-oriented knowledge that facilitates adaptation and is relevant insofar as it supports the continuation of the life of various species (in both social and biological contexts). As such, it also becomes part of the planetary (or even cosmic) project where emerging knowledge opens the way for the humanities and social sciences to think about the multi-species world of future communities that attempts to answer the question of how to live together in conflicts.

Archaeology and Anthropology

Christopher N. Matthews
Montclair State University, Montclair, NJ, USA

Introduction and Definition

This entry addresses the practice of modern world archaeology in relationship to its sister discipline of anthropology. My discussion explores two particular issues. First, I briefly describe a history of some of the shared interests that establish the relationship between archaeology and anthropology. Based in the analysis of material culture and spatial relations, archaeology has long drawn insight and inspiration from the anthropological study of cultural interactions, processes, and systems. I also consider the application of anthropology in the actual practice of modern world archaeology. This work is presented in two frames. The first is the use of anthropological data and approaches in the recovery and interpretation of past people and ways of life through surviving material remains. I focus specifically on cross-cultural studies, whose anthropological perspectives enhance the capacity of archaeology to contribute to the study of colonialism. A second frame is the use of anthropology as a method for developing a reflexive critique of archaeological practice. In recent years especially, a great deal of work has aimed to better understand archaeology as a distinctly modern practice. In one guise, this work looks explicitly to connect archaeology with modern interests in heritage and cultural identity and establishing a record that recognizes diversity within modernity. Another expression is found in work that employs an anthropological perspective to establish archaeology itself as a worthy subject of study. In this work, archaeologists and others examine archaeologists and archaeological projects as cultural practices. The use of anthropology here is a realization of one of the discipline's most basic goals: to critique the "home" cultures and communities that conceived of anthropology and archaeology in the first place and to enhance the capacity of this work to cultivate greater understanding and democratic participation in modern life.

Historical Background

A logical place to start is Lewis Binford's classic and controversial 1963 *American Antiquity* article, "Archaeology as Anthropology." This essay is regarded as a seminal work for "new" or "processual" archaeologists, especially in the United States. While the essay has been critiqued, it still represents one prominent perspective on the practice of archaeology as a branch of anthropology. Binford (1963: 217) states his understanding of anthropology in this way:

Initially, it must be asked, "What are the aims of anthropology?" Most will agree that the integrated field is striving to *explicate* and *explain* the total range of physical and cultural similarities and differences characteristic of the entire spatial-temporal span of man's existence. Archaeology has certainly made major contributions as far as *explication* is concerned. Our current knowledge of the diversity which characterizes the range of extinct cultural systems is far superior to the

limited knowledge available 50 years ago. Although this contribution is "admirable" and necessary, it has been noted that archaeology has made essentially no contribution in the realm of explanation.

For Binford, the purpose of anthropology is to explain "cultural systems," and, as anthropologists, archaeologists should aspire to not only recover, describe, and classify material culture but to employ it as evidence to explain the causes of past activities. Binford sought to reinvent archaeology as a more rigorous scientific pursuit that produced causal explanations based on hypotheses tested against the archaeological record itself. Binford's career as well as that of many of his American peers and acolytes was defined by a scientific struggle to connect the archaeological record to the activities that produced it so that what happened in the past could be known, tested, and ultimately predicted (Schiffer 1976).

Processual archaeologists largely deployed cultural ecology as "anthropology" so that people and their social and cultural contexts were defined by the resources and limitations of their environment. Cultural ecology also places great value on (eco)systemic stability and the importance of adaptation to explanations of human activity. An excessive focus on human-environmental relationships and the concurrent dehumanization of archaeology's subjects fostered a number of powerful critiques of cultural ecology (e.g., Shanks and Tilley 1987; Trigger 1989; Gero and Conkey 1991; Hodder and Hutson 2004). Nevertheless, a kernel of Binford's hope for an anthropological archaeology remains in general circulation. This is the idea that archaeology shares a basic common goal with anthropology: that expressions of humanity, including in and through material objects, are patterned and can be read to reveal influential practices and perhaps underlying rules that produced and reproduced meaning and action. While the cultural ecological approach of processual archaeology situated meaning in the adaptation of societies to their surroundings, the diverse post-processual archaeologies that followed it engendered a more broadly conceived approach to meaning-making in archaeology.

Couched in Marxism, feminism, hermeneutics, and other frameworks, post-processual archaeologies embrace a general notion that understanding agency and subjectivity is essential to the making and interpretation of the archaeological record. In fact, most post-processualists embrace subjectivity, arguing that the intersubjective spaces and activities people work through every day form the basis of active meaning-making in social and cultural life. Post-processual archaeology draws on the anthropological framework that succeeded cultural ecology. This approach has come to be termed "interpretive anthropology," a framework described famously by Clifford Geertz (1973: 5) in this way: "Believing, with Max Weber, that man is an animal suspended in webs of significance he himself has spun, I take culture to be those webs, and the analysis of it to be therefore not an experimental science in search of law but an interpretive one in search of meaning." Interpretive anthropology moves from explanation toward understanding such that even as we live now in our own situated and culturally structured worlds, we may still acquire a perspective on others, both past and present, in which they may be appreciated and understood on their own terms. The focus of interpretative anthropology is less the struggle for resources than the struggles for identity, power, change, and significance.

As interpretive anthropology matured, a significant interest emerged in the situated standpoint of all persons and institutions, including those of the disciplines and researchers working to document and represent diverse cultural worlds. Eventually a reflexive anthropology formed, especially following a set of powerful critiques of the discipline during the 1970s and 1980s. One critique showed the complicity of anthropology within the oppressive and racist colonial regimes where anthropological fieldwork traditionally took place (Asad 1973). A second critique, initially voiced by feminist anthropologists, rejected the capacity for anthropology to produce objective knowledge, insisting that all knowledge is situated and partial, especially knowledge constructed cross-culturally (Moore 1989). A third critique focused on the translation of experience into text and argued for the radical deconstruction of the research position

as not only socially situated but also the result of distinct and under-theorized actions of writing and representation in and about the world (Clifford and Marcus 1986).

Reflexive anthropology fostered new approaches to writing and to the representation of cultural subjects. It also established that the practice of anthropology is itself more than description and interpretation but also is an active way to create meaning in and about the modern world. However, the most powerful transformation to anthropology achieved by reflexive approaches was an acceptance that not only are interpreters (i.e., anthropologists) viable anthropological subjects but subject persons and groups themselves are necessarily valid interpreters of anthropology. Seeking broader inclusion in the discipline and a deeper dialogue about the meaning of anthropology in the modern world, indigenous anthropologies illustrate some of the most basic goals of reflexive research (Smith 1999; Kirch 2006).

In large part modern world archaeology is a post-processual, interpretive, and reflexive field. With access to historical and cultural documents, the textual silence associated with the creators of the prehistoric archaeological record disappears and in fact defines a new rationale for archaeology that aligns it with interpretive anthropology. Given the presence and authority of documents and oral testimony in modern life, archaeology and material culture provide complimentary data that reveal significant contradictions and uncertainties that lie in the spaces between the written and wrought and between the consciously recorded and the simply done (Potter and Leone 1988). Very much informed by interpretive anthropology, modern subjects are considered active social beings whose lives are marked by a rich negotiation with competing regimes of power and identity, such as nation, race, class, capitalism, and modernity. Moreover, with a complex array of documentary and material data at hand, the reconstruction of the interpreting subject is well within the reach of modern world archaeologists. At its best, modern world archaeology brings the world as subjectively conceived by it subjects into view and then deepens it as the statements recorded in documents are articulated with the practical consciousness of actions and artifacts.

Modern world archaeologists are also quite aware that they study the origins of the world as most people know and experience it today. Modern world archaeology thus contains a number of studies cast in the mold of reflexive anthropology. Some of these studies work to bring awareness and significance to what may be termed "minority histories." This sort of research takes as a starting point the fact that the making of modern world has involved the creation of the white western heterosexual male standpoint as the "normal" historical subjectivity. The perspectives and experiences of the modern world of women and nonwhites, as people without history, must therefore be excavated from the spaces where they were confined as secondary and abject and reintroduced as fully participating characters in the narratives of modern life.

A second branch of reflexivity in modern world archaeology researches what may be called "subaltern pasts" (these terms derive from Chakrabarty 2000). In these instances, a reflexive critique of archaeology works to challenge not only the absence of a historical presence for the majority of actors but the inherent biases that lie latent in the archaeological methods and practices we deploy to recover them. As with reflexive anthropology, an indigenous archaeology movement was forged alongside a great deal of productive research and analysis in the field of critical, community, and public archaeology. The remainder of this essay explores varied examples of the use of interpretive and reflexive anthropology in modern world archaeology.

Key Issues/Current Debates

Archaeologies of Colonialism

In most conceptions, anthropology is the study of cross-cultural interactions and subjectivities to provide a relativistic understanding of cultural experiences in different cultural milieus. Anthropology in this vein introduces an important layer of meaning and interpretation that transforms

behaviors that may appear quite strange to outsiders into appropriate, culturally situated responses and actions. For example, Marshall Sahlins' (1985) study of the killing of Capt. James Cook by native Hawaiians in 1779 explains that the event, which lived up to the western conception of indigenous people as dangerous and wild, was rather a playing out of a native Hawaiian conceptual scheme that constructed Cook and his crew as representation of the deity Lono. Similarly, Michael Taussig's (1983) study of Columbian and Bolivian peasants shows that irrational practices like making deals with the devil and baptizing money are rather astute interpretative critiques of the transformations wrought by the capitalist planting and mining industries that came to dominate their communities. Many modern world archaeologists work in comparable cross-cultural contexts that help reveal the contours and constructions of the modern world. While this sort of work may be found in varied contexts, I highlight here the studies that examine the emergence and entanglement of cultures in colonial settings.

One of the most prevalent markers of the modern world is the thousands of intercultural relations that developed with European expansion and colonialism. Most research in this area begins with a conception of colonialism as the interaction of two or more distinct cultural worlds. The result has been an overwhelming majority of studies documenting the impact of colonialism on presumably stable "preexisting" indigenous cultures that underwent substantial change as they became modern. This sense of colonial cultures has undergone serious critique. In a nutshell, this critique illustrates Eric Wolf's (1982) concern with "people without history" such that before contact the worlds of the colonizer and especially the colonized followed secure and essentially timeless traditions that changed only after impact. It is misguided and self-important to think that colonialism instituted changes so substantial that colonized people were irreparably changed by their encounter with Europeans. For one, anthropology explains that all groups face changes and are culturally poised to respond, understand, and control their circumstances. This is the basis of Sahlins' interpretation of culture contact in Hawaii. Second, anthropology also shows that culture does not function outside of the social and historical circumstances in people's lives but is simultaneous and integral to the way history is made. This is what we learn from Taussig's research in South America. As such, we need to take care to recognize that colonialism is more than a context or a set of relations that situates people and groups in certain conceptual cultural worlds; colonialism is also a means of actual cultural production that creates and is created by the specific conditions that enable and control actions and social power through time.

An excellent approach to understanding the dynamics of colonial culture is Kurt Jordan's (2008) study of *The Seneca Restoration* in the early 1700s in New York State. Jordan urges the adoption of two critical standpoints. The first is a rejection of the dominant trope of "cultural decline" attached to the study of indigenous communities in the colonial era. In most instances, researchers posit a "precontact" indigenous people defined by the modern dream of the noble savage, a dream eviscerated as the unprepared native succumbs to modern desires, falters, and ends up destitute if not eliminated altogether. Regarding his study of the Seneca Iroquois, Jordan (2008: 18) points out the principal implication of the trope: "it declares that the only way for the Iroquois to remain Indians was to stay the same." In contrast, Jordan contends that the fact that we call people Iroquois (or another identifier) does not necessarily mean that they need to act in any particularly "Iroquois" way to leave behind important stories about the Iroquois people. Rather, how they struggled to remain a relatively autonomous and empowered community of Iroquois people is what we need to understand.

Jordan also calls for researchers to consider the "local political economy" in the interpretation of colonial lives. Referring to the places and relationships that make up the contexts of their daily activities, such as acquiring, cooking, and preserving food and tools and the maintenance of external relationships (through trade and conflict), he argues that understanding and operating in local contexts made up most of the consciousness

of colonial subjects. A focus on local political economy does not replace a concern for broader-reaching contexts of colonialism or capitalism that are the general interest of modern world archaeologists. Rather, inasmuch as these broader concerns can be understood culturally, it will be in how they emerge in the actual daily practice in localities.

Jordan's study of the Seneca Iroquois in west-central New York State illustrates these standpoints masterfully. Most research argues that the Iroquois' encounter with British and French colonials is a story of decline defined by their participation in the international fur trade interspersed with periodic warfare, which left them decimated by disease and death and unable to reproduce vital cultural practices and remain Iroquois. The consensus is that by the early 1700s, the Iroquois were fully colonized and in this eroded state adopted what they could of European ways of life to survive. By the time they were subject to one of the earliest modern anthropological studies in the 1840s, Lewis Henry Morgan concluded they had become passive and lost the capacity for innovation, i.e., they were no longer Iroquois. Among the most visible effects of Iroquois acculturation were a change in housing and settlement patterns. Pre-contact Iroquois sites are associated with a matrilineal, multifamily house structure known as the "longhouse," built in clustered and often palisaded villages. By the 1700s clustered longhouse villages were replaced with dispersed settlements made up of smaller, sometimes nuclear-family, houses built with European materials. So, when "the people of the longhouse" (Jordan 2008: 13) stopped building longhouses, scholars took this as evidence of their decline.

Jordan counters this interpretation explaining that "many factors previously taken as evidence for acculturation or social disintegration in fact were innovations *beneficial* to Iroquois people" (Jordan 2008: 23). His focus is the Townley-Read site, a component of the dispersed New Ganechstage Complex, located near the western shore of Seneca Lake. The site was established around 1715 in the years after a formal declaration of peace between Britain and France and occupied until the start of new international hostilities in 1754. Over several previous generations, international conflicts created a "landscape of fear" forcing Senecas to negotiate alliances with their Indian neighbors and colonial settlers and armies and, with a constant threat of war, be prepared to protect and/or uproot their settlements. However, after a peace treaty in 1713, palisaded villages were abandoned, and the Seneca moved to the dispersed New Ganechstage Complex consisting mostly of smaller "short longhouses" (Fig. 1).

Jordan argues that the 1713 peace treaty brought about the best conditions the Iroquois had experienced in decades. The shift to a dispersed settlement therefore was a strategic development that allowed established Iroquois cultural practices to be put to use given the current conditions. Dispersed settlements supported greater household autonomy and better integration into the regional political economy. Households avoided a pattern of overusing key resources like firewood and cropland. Seneca women were also closer to water sources and their fields, giving them more time to devote to other productive activities. For example, the archaeological record suggests a greater emphasis on local deer hunting in this era. Deer meat was useful, but given more free time, women also extracted the maximum amount of value from a given animal. Marrow from long bones was collected for storable bone grease. Deerskins were also useful both in the household and as a valuable good in the international fur trade that still operated in the region.

Participation in the deerskin trade is paired with a documented shift in the source of beaver pelts to the Ohio territory and points west. Many scholars assert that this factor also evidences Iroquois decline. Jordan (2008: 341) shows that the western fur trade instead established a very useful "geographic middleman position" for the Seneca, in which good relations with the Iroquois were required for safe passage through their territory to the European trading forts. Iroquois are documented to have encouraged western groups to trade with Europeans in their region, most likely because this would have preserved and enhanced their role in the evolving trade network. Archaeologically this process is visible in a marked increase in the number of red pipestone

Archaeology and Anthropology, Fig. 1 Plan view of a Seneca short longhouse, Structure 1, DRC 1, Area D, Townley-Read site (Courtesy: Kurt A. Jordan)

artifacts which originate from the upper Midwest. More than exotic goods, these artifacts were part of an assemblage that also included glass beads and beaver pelts paid to the Seneca for safe passage through their territory. Notably, red pipestone was not valuable to Europeans at the trading forts so its value was restricted to Native American relations. Moreover, a 1730 document shows that western Indians went out of their way to visit Seneca villages, a record suggesting this was part of an established process of securing an alliance.

In sum, Jordan shows in these data and many others that the early eighteenth-century Senecas were not in decline but strategically situated to take advantage of the opportunities and limitations presented in their cultural world. Their selection of a dispersed settlement pattern suited the conditions of the era and allowed them to employ and adjust key "Iroquois" cultural practices in household management and trade relations. In effect, the evidence of being Iroquois in this case indicates the process of Iroquois people continuously transitioning to become modern within and against colonialism.

A second compelling archaeological study of modern colonialism is Akinwumi Ogundiran's (2002) study of trade beads and cowrie shells in Nigeria and Benin during the era of the African slave trade. Ogundiran works with multiple data sets including myths and legends as well as archaeological material culture to weave a brilliant interpretation of the uses and meanings of cowrie shells. Ogundiran (2002: 431) argues that "material culture, myth, and legends constitute a "cognitive constellation" that shapes the perception of reality and provides insights about the world and about new experiences. In this regard, objects (whether locally or externally derived) are critical to generating, transforming, and

transmitting ideas and values into physical reality. The conversion of ideas into objects and of objects into ideas, however, is a two-way process by which culture is created, codified, and contained." In this approach cultural expressions (both material and ideal) are practical statements seeking to provide stability to the dynamic and unsettled meanings that can emerge in colonial settings.

This study begins with the fact the Bight of Benin/Slave Coast region consumed almost half of the cowrie shells (more than 10 billion) imported through all West African entrepôts. Cowries are an Indian Ocean shellfish species first imported by Portuguese traders to serve as a trade item in Africa. Soon after their introduction, cowries were adopted as a form of currency and thus elevated from a bauble to a foundation of local economies. Ogundiran contrasts the use of cowries with that of glass trade beads that had long served as sumptuary goods deployed by elites to display prestige, cement alliances, and fund attached specialists. Moreover, beads came to stand for preciousness, auspiciousness, good fortune, and spiritual health. Ogundiran offers the following translation of a Yoruba panegyric to illustrate:

Child of one who wakes to thread, one who threads *segi* beads
My father, one who rises at the crack of dawn to thread "groundnut" coral
Child of Owara Aremu, who scatters *segi* beads in the forest
He said it's because of the pluckers of leaves (leaf sellers)
He said it's because of the breakers of sticks (firewoods sellers)
He said it's because of the destitute who traverse the bush far and wide

Beads were the result of hard work and the use of one's wealth to care for those at the margins of society. While self-aggrandizing, elites were praised for their charity and support of the whole community.

The introduction of cowries and their use as currency supported an intensification of commercial activities among an ever-larger proportion of the population that ultimately undermined such reciprocal cross-class relations. Cowries were used for most payments including tribute and bride-price as well as accepted as payments for captives sent to the slave trade. It was the connection between cowries and captive people more than anything else that fractured earlier social relations. One key social factor of cowrie currency was their tie to the emergence of more centralized state power largely supported by elite control of the slave trade. With centralization, the value of cowries stabilized, and their use more became widespread such that while most African commoners rarely owned other Atlantic trade goods by the 1700s, almost everyone in Yorubaland had cowries.

Notably, cowries also became an "embodiment of transformative/ritual potency" (Ogundiran 2002: 440). One story tells of the origins of cowrie money as the result of the peace made between a Benin king, Oba Eresoyen, and the great deity of the seas, Olokun, who "as a reward . . . heaped up cowries to the sky for Eresoyen and they were packed to the palace" (Ogundiran 2002: 441). This myth worked because the connection between the use of cowries and the transshipment of captives represented the basis of a new way of life for people tied to the generation of wealth and power from the ocean. Commoners also told stories that connected enslavement, cowries, and the sea:

In the beginning of the world we had the forge and we forged things, we had weaving-looms and we wove our clothes. . .. we had boats from which we caught fish. We had no guns. We had no cowrie-money (akwa). If you went to the market you took beans in order to exchange them for sweet potatoes. You exchanged something for something else. Then the king brought the cowrie-money. What did the king do in order to bring the cowrie-money? He caught people and broke their legs and their arms. Then he built a hut in a banana plantation, put the people in it, and fed them bananas until they became big and fat. The king killed the people and he gave orders to his servants to attach strings to their bodies and to throw them into the sea where the cowrie-shells (akwa) lived. When the cowrie-shells started to

eat the corpses, they pulled them in, collected the shells, and put the live cowries in hot water to kill them. That is how cowrie-money came to exist (Ogundiran 2002: 443).

Here we see how common people, those most vulnerable to capture, construed a direct human-cowrie conversion. Yet, this myth also captures the rising significance of commercial activity in coastal West African society during this era. With cowries, as with all money, the value of goods shifted from their use in barter to their use in the creation of wealth at the expense of those traded away.

Slave Coast West Africans also found ways to rationalize the transformation of their society toward the global system and an associated shift in the meaning of humanity from lineage and region to the commercial value of persons, enslaved or free, in the market. Ogundiran explains this change through the use of cowries in rituals of self-realization. Just as "Oba Eresoyen is remembered in the oral traditions of Benin as the king who "built a house of money" because he "decorated the walls and palace of his palace with cowries"" (Ogundiran 2002: 445), so did others, including both noble and common people. A significant expression is the proliferation of *Ibori* shrines and *ile orí* or individualized deities constructed with cowries as the main decoration (Fig. 2). The *ile orí* was "the house of the inner head" used to protect individuals from harm by nature or the evil eye, secure their privacy, and ensure their self-respect. The key reference is how cowries supported the individual as the basis of social life and the distinctions between individuals as the result of their autonomous actions: "The centrality of cowries to the making of *Ibori* and its *Ile- Orí* is evidence that cowries became the value register for harnessing the spiritual and temporal powers of successful men and women after the sixteenth century" (Ogundiran 2002: 448). Cowries helped West Africans to conceptualize and enable the transformations wrought to their society by the impact of the slave trade both in the taking of persons and in the commercialization and individualization of everyday experience.

Archaeology and Anthropology, Fig. 2 House of the head shrine (ile ori), dimensions: H. 13 3/4 × diam. 10 in. (35 × 25.4 cm). (The Michael C. Rockefeller Memorial Collection, Gift of the William W. Brill Foundation, 1962. Accession number: 1978.412.459a-c)

Minority Histories: Archaeology, Heritage, and Identity

A very active interest in modern world archaeology lies at the intersection of archaeological research and heritage interests. Heritage is a shared interest among anthropology and archaeology, especially in the field of applied anthropology (Shackel and Chambers 2004). Based on the promise that archaeology can recover new data and build interpretations that compliment as well as challenge dominant narratives of modern history, many archaeologists see their work being about the meaning of past actions to people living now. As applied anthropology, archaeology is used to provide tangible histories and material touchstones in support of the creation and recognition of minority identities in modern life and the construction of paths to the recognition of diverse heritages. Some archaeologists see their work as a form of civic engagement and adopt a distinctly political edge. These approaches deploy archaeological resources to work with minority communities in order to capture their interests in the past

and to present their findings to the broader public with the aim of fostering recognition and social change.

Very good examples of this work come from research connected to the struggle to preserve "unrecognized" indigenous identities in post-colonial modern life. In United States as well as other modern settler nations, the legitimacy of indigeneity is a serious discourse that crosscuts questions about national and tribal identities, race, as well as propertied interests and claims. The basis of recognition in the eastern United States is especially difficult since federal recognition of tribal status demands a continuous and documented official tribal record over four centuries. Being poor, racially outcast, and largely dispossessed of their material and cultural property and heritage, many eastern tribal communities cannot produce the records required for official recognition. Archaeological research on the history of these communities in the modern world, therefore, enters a dialogue on heritage and identity with powerful meanings and results.

The Werowocomoco project (Gallivan et al. 2011) in tidewater Virginia provides a good illustration of this sort of work. Werowocomoco was the capital of the Powhatan confederacy when the English settlement at Jamestown was constructed in 1607. Werowocomoco was also the likely site where Pocahontas saved the life of John Smith, establishing a key origin story about colonial intercultural encounters that most Americans know and embrace. The archaeological discovery of the site in recent years, especially as it was concurrent with the 400th anniversary of the Jamestown settlement, positioned Werowocomoco as a potent symbol to a wide number of groups, including both Native American descendants and non-Indian American patriots.

Gallivan et al. (2011) point to a contradiction that surfaced around the Werowocomoco project between the expectations of indigenous historical and cultural continuity and current trends in anthropological scholarship that challenge essentialist cultural claims. Anthropology in this vein draws attention to the fluid social networks and strategic adaptations groups adopt to preserve autonomy and power during stressful times. The problem for unrecognized tribes such as the Pamunkey and the Mattaponi is that, while this sort of research may produce a more accurate, decolonized depiction of their history as people who equally contributed to the making of the modern world, it undermines the requirements for recognition that they exist still as "fixed, bounded and historically continuous entities" (Gallivan et al. 2011: 12). As such, Native American collaborators in the Werowocomoco project "publically represented themselves and their communities in terms of tightly bounded, internally homogenous tribal identities" (Gallivan et al. 2011: 12).

Despite this context, the research team still found useful insights and approaches that helped to construct a novel understanding of an indigenous life during the early colonial era. Challenging preconceptions that the Powhatan confederacy was a regionally organized, hierarchical chiefdom, archaeologists now believe that the network of Indian communities was framed in more local terms with groups forming alliances and other "foreign relations" without the overarching authority of a centralized chief. With this perspective in mind, Gallivan et al. (2011: 19) consider the community at Werowocomoco and their descendants have long practiced "creatively incorporating cultural elements including colonists, Christianity, and (most recently) archaeology, while retaining meaningful connections to place as well as kinship ties that stretch across diverse communities." While the results of this project and the collaborations and political actions with which it is engaged are not yet fully realized, a view of how modern world archaeology intersects with the complexities of intersecting and diverse heritages is very evident.

A second approach to heritage-driven research in modern world archaeology draws from a more explicit and political engagement with the process of building community collaborations as social action. Through the negotiation of a shared authority over research and presentation, collaborations with descendant and local communities often serve to empower not only their recognition but novel forms of knowledge useful to

understanding modern lives both past and present. The Hampden Community Archaeology Project (HCAP) in Baltimore, Maryland, is a wonderful example of this work in the context of industrial working-class heritage (Gadsby and Chidester 2011). The Hampden section of Baltimore is a former industrial zone and working-class district that thrived in the late nineteenth and early twentieth centuries. After the 1920s most factories closed and residents had to look elsewhere for work. By the late twentieth century, Hampden's industrial history became noteworthy, though this was based in stories of the district's industrial and technological achievements and not stories about its working-class residents. As is common in post-industrial districts, this history was closely tied to the renovation of mill buildings into high-end studios and offices and the opening of new restaurants and trendy shops as Hampden was gentrified for use by the middle class. While the working-class history of the neighborhood is largely neglected, it does make an appearance at "HonFest" an annual event that "lampoons an imaginary blue-collar experience by disseminating inaccurate and cartoonlike images of working class men and women" (Gadsby and Chidester 2011: 106) (Fig. 3). The HCAP seeks to redress this slighting of the heritage of the working-class residents, who have always formed the core of the Hampden community.

Gadsby and Chidester (2011: 107) distinguish between public heritage, that which is marketable and often the focus of heritage and urban development professionals, and private heritage "in which the past is dynamically linked to the present, with heritage values interpreted and identified by community members rather than outsiders." Focused on landscapes, housing, and fixed historical associations, public heritage encourages forgetting as it separates people and places. Private heritage, however, promotes remembering as it is based on the people and relations that connect past and present and thus give historical contexts to places as they are actually lived.

In addition to excavations at sites associated with the historic working class of Hampden, the HCAP also developed a number of noteworthy outreach programs to illustrate and promote an appreciation of the private heritage in Hampden. These included a series of public history workshops, a project blog, an oral history project run with high school students, and a program that paid city youth to work on the project. These resources provided community members with a chance to participate, publicly share their interest in

Archaeology and Anthropology, Fig. 3 HonFest 2004. Hamden, Baltimore (Photograph courtesy David A. Gadsby)

Hampden's working-class heritage, and criticize how this heritage is ignored by outsiders. These useful critiques enhance the capacity of the archaeological project to engage in informed social action. One example of this was the creation of an exhibit on working-class women's history in Hampden to be mounted during HonFest, which provided a counter-narrative to the disparaging public heritage otherwise represented at this event.

Subaltern Pasts: Diverse Meanings of Archaeology in the Modern World

There is one additional anthropological method used to engage the cultural complexity of the modern world in archaeology. This involves understanding the contemporary landscape of knowledge production that enmeshes archaeology in modernity (Thomas 2004). Taking a cue from reflexive approaches in anthropology, some modern world archaeologists have conceived projects that consider archaeology itself as a subject of study. While some have engaged in ethnographic research of archaeologists at work (Edgeworth 2006), others pursue ethnographic research on the contexts that construct archaeology as a discipline and practice as well as the activity of specific persons in the modern world. From the latter especially, important insights on the intersection of archaeology and modern life have emerged that very well may change the discipline's future.

This line of research may be couched under Lynn Meskell's (2005) term "archaeological ethnography." For Meskell, there are two critical elements that define this approach. The first is an interrogation of the relations between archaeology and "the locals." Long associated with archaeology as laborers, constituencies, sources of "traditional" knowledge, descendants, and stakeholders, archaeological ethnography seeks to broaden the scope of "local" relations as they are defined by the global and local scales of the modern world. At the global scale, "locals" are defined by diverse and specific geopolitical positions that situate them in ethnic, racial, and class histories of place and locality. According to Meskell (2005: 82), "locals" are not passively engaged with their conditions but "directly enmeshed in their own critical reformulations, political negotiations, and constitutions of theory and interpretation." In addition, local communities engaged with archaeology are typically internally diverse, crosscut by gender, age, and class dynamics that will necessarily affect relations with archaeologists and other outsiders. Archaeological ethnography works through these dynamics to establish the proper cultural fields in which archaeology participates.

One result of this approach for Meskell was the clear pictures of archaeology that "locals" had in mind when she approached them about her project at Kruger National Park in South Africa. Meskell's interest was in developing a proper picture of the cultural meanings and interests that neighboring communities, many of whom had been displaced by the colonial and apartheid regimes to create the park, held for archaeological sites within the park. Intending to discuss this project with residents of a Malatji village, she was directed to a courtyard where women were preparing a plaster courtyard floor. Meskell realized they were showing her traditional Malatji construction techniques or what they thought an archaeologist would be interested in seeing in their village. A similar example of cross-cultural confusion arose when her team reached an impasse while interviewing Malatji elders. The new chief expressed reservations about sharing the elders' stories because of a history of their cultural knowledge being used against them, especially in regard to land claims. Meskell (2005: 92) puts it this way: "in most contexts the taxonomy of "homeland" would be a positive one inflected with concepts of tradition, ancestry, and indigeneity, whereas in South Africa it is steeped in a dystopian history of dislocation and disenfranchisement."

A second critical element for Meskell is the interrogation of the discursive field archaeology occupies. In archaeological ethnography, researchers shift their attention from an interest in past dynamics to the notions and uses of "archaeology" and "the past" in contemporary culture. While the past is a vital resource for building heritage in the present, the structure of the past and even what constitutes being "past" are

regularly debated. The structure of the past is defined in the conflicts between unified and fractured tellings of history: whose history is privileged? How and why are others left out? Does the acceptance of diversity in history require multiple histories or can a broader inclusive history be built? The question of what is actually past versus what is still present is one with especially great relevance in modern world archaeology. In fact, a defining characteristic of modern world archaeology is that the issues and topics driving research have direct relevance to the present. Topics such as capitalism, colonialism, industrialization, racism, gender and sexual bias, class formation, and oppression can all be situated in both past and present, often with clear ties between what happened before and why and how things are the way they are now (Hamilakis and Duke 2007; Matthews 2010; Voss and Casella 2012).

More pointed than expressions of cultural continuities, the question of what makes the past is especially significant when the problem is whether a people still exist and therefore whether the claims of those living now need to be addressed. Similar to the question of recognition in the Werowocomoco project discussed above, Meskell found a sharp divide between natural and cultural history in Kruger National Park that removed responsibility from park managers for the maintenance of archaeological sites or from having a working understanding of the relevance of archaeological sites to nearby local communities. The additional complexity here comes from basic questions that emerge about what counts as archaeology and who is responsible (and how) for establishing its relevance in the contemporary world.

My own work with the descendant mixed-heritage Native and African American community in Setauket, New York, explores some dimensions of archaeology as a public discourse alongside its role as a method for recovering histories lost to modernity (Matthews 2011). This project began as a collaboration between a community-based historic preservation group, Higher Ground Intercultural and Heritage Association, Inc., and the Center for Public Archaeology at Hofstra University (the collaboration is now with the Center for Heritage and Archaeological Studies at Montclair State University). From the start the project was community-driven, in that Higher Ground sought to create an independent story of their community that captured what its leaders felt was a disappearing resource. Since the 1960s, the mixed-heritage minority community in Setauket has seen a great deal of change as their population dropped from more than 40 families to fewer than 15. The problem is that during this time the Setauket area became suburbanized, a process that introduced more people and commercial development in the local area. New people and resources in turn led to an increased demand for housing and municipal services that in turn drove up property taxes. The Native and African American community were not prepared for these changes, and many have since left the area for less expensive places to live. While the process of gentrification is common on the American landscape, in this case, the community being removed is one that has distinctly deep local roots, having been present in the area since colonial settlement in the 1660s, if not long before, given their Native American ancestry.

This community's story is also connected to another local effort to control suburbanization: the creation of a series of historic districts in the area that have protected historic sections of Setauket from demolition. These districts have preserved a wide range of structures dating to the colonial and postcolonial eras of the area that help to give Setauket an aura of the past that it uses to distinguish itself within the larger region. It is notable that the sections excluded from these historic districts were those areas where the minority community, who have always been there, lived. In one case the neighborhood was already torn down and replaced with a strip mall; in another case, the community was already removed in order to create an all-white elite enclave; and in the third, the area known as east Christian Avenue, where those who remain still live, was excluded because of its lack of properly "historic" structures. In the end, the historic minority community was surrounded on all sides by an official historical landscape that made virtually no mention of them.

In response, Higher Ground petitioned for the creation of the Bethel-Christian Avenue-Laurel Hill historic district in 2005 so that the last stronghold of the historic Native and African American community could be preserved. This act not only added a minority component to the local historical landscape, it created a social context for creating and telling a separate story about the past in Setauket. This is how the collaboration between Higher Ground and Hofstra University came about. Higher Ground deliberately sought an outside institutional partner with which to create an independent and critical story of Setauket as a historical place. The partnership therefore was formed not only to recover archaeological and historic data but to create a new perspective on minority history within a space where the official history is routinely and genuinely celebrated by the majority community. Moreover, the purpose of our project does more than challenge the mainstream story about the past in Setauket but also makes plain that neglecting the minority community in local history is akin to neglecting their well-being and survival in the present.

In words of Mr. Robert Lewis, President of Higher Ground, archaeology provides an opportunity to do something "unconventional." For his whole life, Mr. Lewis lived in a Setauket that relied on a simple historical thread tied to its colonial and rural history, its association with actions during the American Revolution, and a long process of slow capitalist development that had always found a place for his people, although at the bottom end of the socioeconomic scale. When he heard this same story from white preservationists as he sought their help, he realized that the story itself was very much part of the problem because it was not the same resource in his community than it was for his white neighbors. He needed a story of his own that could excite his community and inspire them to protect their heritage despite the obvious challenges.

Regarding archaeology Mr. Lewis said, "because it is unconventional opportunities for exciting discoveries exist" (Matthews 2011: 50). So, in this project we not only share our findings and include community members in the process of creating knowledge about the past but seek explicitly to engage them in the association between archaeology and discovery that Mr. Lewis keyed into. Archaeology emerges through a different process and from a different archive than the traditional stories circulating in Setauket, and the sites and artifacts we discover are directly connected to members of their community. These sources and connections support a place for an indigenous knowledge not predicated on the survival of ancient traditions alone. Rather, it is based on the same process of discovery that has fueled mainstream knowledge and fascinations with the past but practiced in this case by subalterns who have traditionally been excluded from making discoveries and contributing to the making of modern places of heritage. Thus, in this case, archaeology is both discursively and practically in the hands of the community and therefore provides them with a tool to do more than represent diversity but also to create it.

Future Directions

This entry has considered the relationship between anthropology and modern world archaeology, and the studies reviewed were selected to provide a view on where the use of anthropology by modern world archaeologists is heading. The several examples show how the use of the interpretative and reflexive anthropological approaches creates potent frameworks for creating knowledge about and understanding of modern lives. One specific use of anthropology is in the cross-cultural analysis of modern colonialism where archaeology provides insight on local political economies and reveals strategic indigenous cultural practices that complicate master colonial narratives of decline and acculturation. A second anthropological approach lies in the development of heritage diversity in modern life. Considering examples of Native American and working-class struggles for proper cultural recognition, archaeology is shown to function as a tool for both research and social action and to provide a useful means for supporting cultural claims that complicate the histories of minorities that dominate modern life. Also discussed was the possibility of

modern world archaeology to address the cultural realities that situate archaeology and archaeologists. These realities include miscommunications of the role of archaeology in the new South Africa and the capacity of subaltern people in New York to appropriate the idea of "archaeological discovery" to create an independent and politically useful indigenous history.

Anthropology serves modern world archaeology by providing frameworks that situate modern people, practices, disciplines, objects, and ideas in specific and productive material and cultural relations. In turn, archaeology activates a new archive of data that brings into view actual and possible counter-narratives that complicate our understanding of the experiences of modern life and the ability of archaeologists to act as modern people coeval with the people and pasts that constitute their research and lives.

Archaeology and Antiquarianism in China

Phillip Grimberg
Department of Chinese Studies, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany

Introduction

Antiquarianism has long been intertwined with historical and historiographical narratives in China and can be understood as an attempt to bridge the divide between the present and the past through written and material sources. Harking back to the primal stages of dynastic rule in China, history and historiography played a vital role in political and philosophical thought and speculation. Thus, a concern for ancient artifacts and the material residues of the past to undergird historical scholarship has formed an integral part of Chinese historical thought.

Although we can find traces of collecting and proto-antiquarian pursuits from as early as the Han 漢 dynasty (206 BCE-220) – with a first apogee during the years of the Wang Mang 王莽 (r. 9–23) interregnum (Falkenhausen 2013) and another crucial period during the Tang dynasty (618–906) in which the preoccupation with the material remains of the past facilitated the development of an interest in antiquarian studies that laid the foundations for later antiquarian and proto-archaeological research – it was not until the Song 宋 dynasty (960–1276) that antiquarianism became both a fathomable concept as well as a past-time of the elite. Collecting and studying ancient objects became associated with the idea of comprehending and retracing the Way (*dao* 道), the natural order of the universe, and maintaining the order of the world and the cosmos. By collecting and studying antique objects, which were regarded as embodiments of political and moral authority, the antiquarian collector could bridge the divide between him and the idealized past. By virtue of this appropriation, he therefore gained moral gravitas, demonstrating a firm and historically recurrent belief in the moral and educative capacity of ancient artifacts (Grimberg 2019). Collectables were perceived as documents, as cultural legacy and material evidence of the past rather than objects of art. Therefore, books, but also ritual bronzes, jade objects, and other artifacts, were regarded as being the same type of objects. Their main function was not to please the senses or to inspire awe and admiration in those who looked at them, but to record events and deeds of the past. By collecting ancient objects, the antiquarian aligns himself with the (idealized) past and the (virtuous) people that owned the objects before him. Consequentially, the antiquarian collector is eager to preserve and pass on the objects he collects. Antiquarian studies and collecting thus correlate with maintaining and emulating the order of the world and the cosmos, as the cosmos is reflected in the objects collected. By collecting and studying ancient objects, the antiquarian symbolically protects the world from chaos (*luan* 亂).

Not only, however, were ancient objects regarded as material evidence of the past and exemplifications of cosmic forces, but also as instruments for education. Hence, antiquarian

collecting was seen as a means of fostering talent and disseminating knowledge, thereby promoting learning and virtuousness which were considered to be among the guiding principles in becoming a Confucian Gentlemen (*junzi* 君子).

While in later centuries, especially during the Yuan 元 (1276–1368) and Ming 明 dynasties (1368–1644), the majority of scholars showed little interest in antiquarian studies per se, it was during the Qing 清 dynasty (1644–1911) that antiquarianism flourished, reaching the apex of activity in the eighteenth century. Whereas the best part of the nineteenth century witnessed a more textually and linguistically oriented approach to history and historical texts, it was during the first decades of the twentieth century that modern field archaeology was introduced to China for the first time.

Definition

Antiquarianism can be defined as the study of history through objects such as antiquities, ancient artifacts, and manuscripts, while the term *archaeology* describes the scientific study and excavation of material and environmental remains of past human life and activities.

In China antiquarianism or *jinshixue* 金石學, literally the "study of bronze and stone," is first used to describe the activity of studying historical artifacts, mostly bronze inscriptions and inscriptions on stone stelae – hence the term, in texts of the late Tang and early Song dynasty. The modern Chinese term for archaeology, *kaoguxue* 考古學 or "investigating antiquity," on the other hand, is an old term borrowed from the title of a catalogue of collectibles by Song scholar Lü Dalin 呂大臨 (1046–1092) that was only reintroduced to Chinese scholarly discourse from Japan in the second half of the nineteenth century where it had been adopted for the phenomenon of western field archaeology. Until the beginning of the twentieth century both terms have been used interchangeably (Visconti 2015).

Historical Background

The Tang Dynasty

Although collections of historical and/or precious objects, of so-called ecofacts, and curios as well as accidental discoveries of relics and artifacts by peasant-farmers, well-sinkers, or builders, antedating (proto)archaeological scholarship of later dynasties, have been documented in China since the 1st millennium BC, antiquarian interests only started to form during the Tang dynasty. With Confucianism gradually substituting Buddhism as the philosophical and social common denominator after a period of predominantly Buddhist leanings of the Chinese court, collecting ancient artifacts and *objects d'art* became a pastime of the elite (Demattè 2011).

The discovery of a set of drum-shaped stones engraved with archaic characters describing the hunts of the dukes of Qin dating from the late Spring and Autumn (Chunqiu 春秋, 771/770 to 481/453 BCE) or early Warring States (Zhanguo 戰國, 481/475/453-221 BCE) period, which were unearthed during the founding years of the Tang dynasty, furthered a new interest in antiquarian studies and ancient history. The so-called "Stone drum inscriptions" (Shigu wen 石鼓文) count among the earliest known stone inscriptions in China. They boast a number of poems in four-syllable verses with some 700 characters in large seal script (dazhuan 大篆). During the middle and late Tang historians commented on the stones and copies of the inscriptions were widely circulated among scholars (Mattos 1988), fuelling debates about history and historiography.

An example of what might be regarded as the earliest documented evidence of antiquarian interest during the Tang dynasty is a collection of coins unearthed from a hoard in Xi'an, dating to the year 755. It contained, among other things, coins from the Eastern Zhou to the Northern and Southern Dynasties period (Nanbei chao 南北朝, 420–589) as well as specimen from Turfan, Japan, and even Byzantium. Although Falkenhausen (2013) rightly argues that we cannot know the collector's intention in putting together his collection we can, however, infer that it is the result of a systematic, (proto-)antiquarian approach to collecting rather

than a mere bricolage of random, unrelated objects.

In the wake of the so-called *guwen* (old text 古文) movement initiated by the prominent Tang scholar and poet Han Yu 韓愈 (768–824) that promoted the use of pre-Han writing styles in literature and the strengthening of the Confucian orthodoxy, studies of ancient texts and antiquities alike became the nucleus of a new scholarship that evolved around ancient history, palaeography, and object studies, eventually leading to the development of antiquarian learning that unfolded during the Song dynasty.

The Song Dynasty

Antiquarian pursuits of scholar-officials and members of the social elite during the Song dynasty were based on the studies and collections of their Tang progenitors. An increase in building and engineering endeavors that was due to economic growth and a high-impact level of prosperity at the beginning of the dynasty led to more and more archaeological discoveries of ancient relics, sparking an ever growing interest in the material legacy of the past (Rudolph 1963).

While during the centuries following the Qin 秦 (221-206 BCE) and Han-Empires up until the end of the Tang dynasty the court has been the driving force of collecting ancient artifacts and predominantly shaped the tastes of the elite, it was during the first century of the Song dynasty that the court gradually lost its status as the center of gravity for antiquarian studies and collecting, and affluent private scholars came to dominate the scene instead. Although the founding Emperors of the Song had seized the collections of conquered local dynasties of the Five Dynasties and Ten Kingdoms (Wudai shiguo 五代十國, 906–960), uniting their treasures and incorporating them into the Imperial collection in order to demonstrate the new dynasty's cultural hegemony, it was only during Emperor Huizong's 徽宗 (1101–1125) reign that the court regained its former significance in collecting antique objects while at the same time reclaiming the prerogative of cultural sovereignty (Buckley-Ebrey 2014; Hsu 2013; Buckley-Ebrey 2008). Simultaneously, scholar-officials like Ouyang Xiu 歐陽修 (1007–1072) and Su Shi 蘇軾 (1037–1101) revived the *guwen* movement of the Tang and advocated the strengthening of the Confucian orthodoxy and classicizing learning.

The systematic documentation of collected objects and antiquarian catalogues both private and Imperial also emerged during the Northern Song for the first time. Among the earliest catalogues of this kind are the *Jigulu* 集古錄 by Ouyang Xiu, dating from 1061; the *Xian Qin guqitu* 先秦古器圖 by Liu Chang 劉敞 (1019–1068), dating from some time before 1068; the *Kaogutu* 考古圖 by Lü Dalin, which was posthumously published in 1092; Zeng Gong's 曾鞏 (1019–1083) *Yuanfeng leigao jinshilu* 元豐類稿金石錄 from sometime between 1078 and 1085; Zhao Mingcheng's 趙明誠 (1081–1129) *Jinshi lu* 金石錄 from 1104; as well as Xue Shanggong's 薛尚功slightly later *Lidai zhongding yiqi kuanshi fatie* 歷代鐘鼎彝器款識法帖 from 1144 and Zheng Qiao's鄭樵 (1104–1162) *Tongzhi jinshi lue*通志金石略 from 1157 (Visconti 2015).

One of the most important precursors and patrons of antiquarian studies, collecting, and (proto-)archaeology among Chinese antiquarians, however, was Emperor Huizong, the penultimate Emperor of the Northern Song (960–1127). As one of the first collectors in Chinese history, he commissioned and published extensive catalogues of his collections. Huizong started collecting when he still was only a prince, influenced by his maternal uncle Wang Shen 王詵 (1048- c. 1103) who assembled a premier collection of books, ceramics, bronzes, and jades himself (Buckley-Ebrey 2008).

Among Huizong's catalogues the most prominent are the *Illustrated Catalogue of Antiquities of the* Xuanhe-*Era* (Xuanhe bogutu 宣和博古圖), the *Catalogue of Paintings from the* Xuanhe-*Era* (Xuanhe huapu (宣和畫譜), the *Catalogue of Calligraphies from the* Xuanhe-*Era* (Xuanhe shupu 宣和書譜), and the *Catalogue of Rocks from the* Xuanhe-*Era* (Xuanhe shipu 宣和石譜).

The first of these catalogues, the *Illustrated Catalogue of Antiquities of the* Xuanhe-*Era*, edited by scholar-official Wang Fu 王黼 (1079–1126), was published in 1123 during the

Xuanhe reign period of the Emperor (1119–1125), as were all of the other aforementioned catalogues; hence their respective titles. The *Illustrated Catalogue of Antiquities of the* Xuanhe-*Era*, however, describes some 55 categories of objects from the imperial collection, including bronzes of such types as *zun* 尊, *yan* 甗, *pu* 鋪, *ge* 鬲, *ying* 罌, *qing* 磬, *jian* 鑒, and *ding* 鼎 etc., totaling 840 objects. They date from between the Shang/Zhou dynasties through the Tang. Besides categorizations of the objects and their respective approximated chronologies and age estimates, the catalogue offers skillfully illustrated descriptions and comments on provenance and measures such as height, diameter, volume, and weight, as well as information concerning the material used and the decorations applied. Furthermore, it provides transcriptions and comments on the ancient inscriptions. It is, indeed, the very first catalogue of this kind, being a thoroughly executed scholarly assessment of the objects it lists and a demonstration of the Emperor's keen interest in his collections and the objects he collected. In order to enlarge and enhance his collections Emperor Huizong deployed professional agents who searched the country for the most outstanding pieces and brought them back to court. Some artifacts were dug up in imperially commissioned archaeological excavations, others were given as presents to the Emperor by local dignitaries and aspiring officials. In some cases, recasts and copies of artifacts of outstanding beauty, rarity or value were made and incorporated into the Imperial collection (Buckley-Ebrey 2010).

The *Catalogue of Paintings from the* Xuanhe-*Era* describes 6396 paintings by 230 masters in the Imperial collection, dating from the Wei-Jin 魏晉 periods to the Northern Song. The catalogue specifies genres and categories by which paintings and masters are listed chronologically according to their rank, merit and quality, which were measured in descending order by the categories of "divine" (shen 神), "wonderful" (miao 妙), and "able" (neng 能).

The *Catalogue of Calligraphies from the* Xuanhe-*Era* is the catalogue of the Imperial calligraphy collection and contains chronologically arranged entries on calligraphies executed in the seal script (zhuanshu 篆書), clerical script (lishu 隸書), standard script (kaishu楷書), cursive script (xingshu 行書), grass script (caoshu 草書), and the bafen 八分-style of the standard script as well as biographies of calligraphers and masters from the Wei-Jin period up to the Northern Song, which are discussed due to their rank, merit and overall quality. In total the catalogue contains 1220 works by 247 calligraphers.

Lastly, the *Catalogue of Rocks from the* Xuanhe-*Era*, the shortest of all of Huizong's catalogues, contains 61 entries on ancient rocks and rockeries of various origins, shapes, and sizes that were to decorate and adorn the Imperial parks and gardens. It lists the rocks' measurements, their visual nature and qualities, their provenance, their site of installation, and, if they happened to have one, the inscriptions they bore (Buckley-Ebrey 2014).

Most catalogues of the time combine visual representations like textual transcriptions, rubbings, and printed images of the objects with a systematic, typological approach of classification that is backed by philological and historical scholarship.

During the Northern Song dynasty antiquarian approaches towards antique objects generally changed from classifying them as treasured relics or artifacts to material evidence of the past that seconded the traditional text-based historical inquiries of classical learning, while at the same time fusing notions of historicity and aesthetic concern deeply ingrained in Northern Song antiquarian scholarship with the (re-)awakening of a Chinese identity in a time of geopolitical uncertainty with foreign dynasties at the Empire's doorstep.

While after the abduction of the Imperial court to Manchuria following the plight of the Jurchen's siege and sacking of Kaifeng in 1127 and the reestablishment of the court in the southern capital of Lin'an (Hangzhou) shortly afterwards, collecting and antiquarian pursuits in general wavered, Northern Song catalogues were continuously reprinted and widely circulated among members of the elite. However, during the Southern Song intellectual concerns shifted from the object-driven antiquarian interests of their

forebears to more metaphysically inclined philosophical debates that led to a gradual decline in the prestige of collecting and antiquarianism. Thus, antique objects, formerly venerated for their moral authority and educative capacities, were relegated to the status of aesthetic props, valued for their entertaining qualities and artistic merits only. Accordingly, archaic forms and ornaments in decorative objects were to define the taste and aesthetics in the arts and crafts for the remainder of the Southern Song, affixing the visual signatures of the past to the tastes of antiquarians and collectors alike.

The Yuan and Ming Dynasties

After the end of the Southern Song dynasty in 1276, the majority of former court officials, scholars, and Song loyalists refused to take up office under the new Mongol regime and thus retreated to retirement – some even committed suicide. In light of the dynasty's fate, antiquarian pursuits were largely discarded in favor of more serious political and philosophical speculation about the future prospects of the realm under foreign rule. The Mongols on the other hand, while generally being rather indifferent towards Chinese cultural traditions, boasted three prominent members of the Imperial clan that fashioned antiquarian studies during the Yuan dynasty. The first, Princess Sengge Ragi 祥哥剌吉 (1283–1331), was the great-granddaughter of Kublai Khan 忽必烈 (1215–1294) and an avid collector of ancient objects of Imperial provenance. Thus, the Princess eagerly retrieved objects that formerly were part of the collections of the Song court and, specifically, personally belonged to Emperor Huizong of the Northern Song (or allegedly did so). After his demise the bulk of his collections was either destroyed by the Jurchen invaders or dispersed and sold off. Some 200 years later Princess Sengge Ragi managed to locate and retrieve a great many of objects of Imperial Song provenance and incorporated them into the collections of the Yuan court, which were later to become the foundation of the Ming and ultimately Qing Imperial collections. The second, her son-in-law, Tugh Temür (1304–1332), who became Jayaatu Khan or Emperor Wenzong 文宗 in 1328, was an accomplished poet and a dedicated antiquarian himself who established the so called Kuizhang Pavilion (Kuizhang ge 奎章閣), an academy and treasury in the palace grounds in the Mongol capital of Dadu 大都 where he kept and studied his collections of bronzes, jades, ceramics, and books. The third member of the Mongol Imperial clan who showed an interest in antiquarianism and collecting was Toghon Temür or Emperor Huizong 惠宗 (1333–1370), the last of the Yuan Emperors. Much like his predecessor Emperor Wenzong, Toghon Temür instituted an Imperial academy called Xuanwen Pavilion (Xuanwen ge 宣文閣) where he conversed with scholars and fellow antiquarians and kept his collections of antique objects, calligraphies, and paintings (Shambaugh Elliot and Shambaugh 2005).

Admittedly, his successors of the Imperial house of Zhu 朱 did not show much interest in antiquarian studies, archaeology or collecting altogether. However, the Ming dynasty in general witnessed a phase of rapid and profound socio-economic change including a considerable growth of population, an overall increase in wealth, and the emergence of a new affluent "middle class" of merchants with access to education and the time and money for leisurely pursuits. Thus, antiquarian studies and collecting became more and more common among tiers of Chinese society that were formerly barred from the exclusive circles of elite pastimes. While during the first century of Ming rule only very few antiquarian manuals were published – like Cao Zhaos 曹昭 (fl. 1370–1400) *Gegu Yaolun* 格古要論, a comprehensive collection of bronzes, paintings, calligraphies, stone rubbings, jades, ink stones, metalwork, ceramics, lacquer ware, textiles, and musical instruments that became very influential among fellow antiquarians and collectors of the day – it was only during the second half of the Ming dynasty that private collectors issued antiquarian catalogues and manuals of their collections in larger numbers. Among these was Gao Lian's 高联 (1573–1620) treatise *Zunsheng bajian* 遵生八笺, published in 1591 as well as Zhang Yingwen's 張應文 (1530–1600) *Qingbi zang* 清閟藏, published in 1595. Others, like

critic and Confucian reformer of the Ming-Qing transition Huang Zongxi 黃宗羲 (1610–1695), published his collections of rubbings of tomb inscriptions in his *Jinshi yaolie* 金石要例 in 1658, some 14 years after the demise of the Ming, while philologist and geographer Gu Yanwu 顧炎武 (1613–1682) published two compendia of epigraphic texts on bronze vessels and stone stelae, the *Qiugulu* 求古錄, containing rubbings and transcriptions of texts from fifty-six stone stelae from the Han to the Ming dynasty, and the *Jinshi wenzi ji* 金石文字記, dealing with bronze vessels from the Shang and Zhou dynasties as well as stone inscriptions from the Han to the Tang dynasty.

Whereas during the Late Ming the elite's interest in bronzes and antique objects generally wavered in favor of a more linguistically driven concern for the textual transmission of what was considered the original teachings of the Confucian orthodoxy of Han and pre-Han times unspoiled by Buddhist and Neo-Confucian additions – artifacts were no longer considered historical sources in their own right, rather, they were seen as "superfluous things" (zhangwu 長物) (Clunas 2004) and "ancient playthings" (wangu 玩古) that yielded no value beyond aesthetic pleasantry – reprints of Song catalogues of antiques became collectibles themselves. Rather than perpetuating antiquarian pursuits or sparking an interest in archaeological research, catalogues found their way into book collections of the Late Ming where they were grouped with other connoisseurial manuals of the time like the *Pinghua Pu* 瓶花譜 by Zhang Chou 張丑 (1577–1643), published in 1595, or Yuan Hongdao's 袁宏道 (1568–1610) *Pingshi* 瓶史, published in 1599.

Although antiquarian and archaeological studies remained in a stalemate during most of the Ming, the more evidence-oriented approach of the philological reform movement of the Ming-Qing transition (Elman 1984) and the shift in paradigm from philosophical and metaphysical speculation to practical research and "evidential scholarship" (kaozhengxue 考證學 or kaojuxue 考據學) of the time (Hammond 2012; Elman 1984) was to prompt an increasing concern for archaeological studies and scholarly antiquarianism that first emerged during the early Qing dynasty, reaching its apogee in the eighteenth century.

The Qing Dynasty

Early precursors of Qing textual criticism like aforementioned scholar Gu Yanwu, founder of the so-called "School of Han Learning" (Hanxue 漢學), as well as Huang Zongxi, Yan Ruoqu 閻若璩 (1636–1704), Hu Wei 胡渭 (1633–1714), Mao Qiling 毛奇齡 (1623–1716), Wan Sida 萬斯大 (1633–1683), or his brother Wan Sitong 萬斯同 (1638–1702) and others advocated the use of an inductive method of textual criticism, including the use of material evidence and archaeological finds in order to adjust and re-evaluate canonical interpretations of history and to gain a firmer, more evidence-based grip on the lore of the Classics and their inherent meanings. This tide of textual criticism, ultimately aimed at improving the ruler's capacities to govern properly through a thorough and unswerving grasp of the past, simultaneously led to an increase in antiquarian and archaeological research that was to replace traditional notions of historical scholarship as a means for comprehensively and systematically reconstructing the past (Guy 1987).

While the first two Emperors of the new dynasty, Shunzhi 順治 (1644–1661) and his son Kangxi 康熙 (1662–1722), who otherwise was rightfully considered a wise, learned ruler, did not pay much attention to antiquarianism or archaeological research, the third Emperor of the Qing, Yongzheng 雍正 (1723–1735), on the other hand, showed a keen interest in collecting and antiquarianism and was the first of the Manchu rulers to have his decorative curios and antique objects studied and portrayed in detail. In so-called "Illustrations of Ancient Playthings" (Guwantu 古玩圖) Emperor Yongzheng and his fellow antiquarians documented their collections in pictorial inventories that depict a wide variety of objects ranging from books and handscrolls to ceramics, jade and bronzes as well as exotic items such as coral, shells or rocks and other ecofacts.

It was, however, his son, Qianlong 乾隆 (1736–1796), who became the most prolific and avid collector of ancient artifacts among Qing

Emperors and a knowledgeable and keen antiquarian, setting the stage for a lifelong political and artistic program that was to encompass both his roles as an absolute ruler over the at the time richest country in the world and that as an aesthete, a scholar, and a collector who dedicated part of his time and wealth to antiquarian studies and collecting (Grimberg 2019; Holtzwarth 2005; Rawson 2005). The Emperor was a major patron and important preserver and furtherer of the arts and culture of the time. For the first time in the history of antiquarianism in China Qianlong aimed at putting together a "universal" collection, including objects from Japan, India, South East Asia, the Ottoman Empire, and Europe such as furniture, clocks, automatons, technical and optical instruments, carpets, mirrors, paintings, tapestries, musical instruments, weapons, books, etc., as opposed to earlier collections that predominantly focused on particularly *Chinese* objects. Most "foreign" objects in his collections came as presents from missionaries or envoys or were specially commissioned for the court and shipped to the Emperors' palaces.

The objects he collected identify the Emperor as supreme scholar as well as the guardian and preserver of China's historical and cultural heritage and demonstrate his patronage over the cultural production of his country. Gaining the cultural prerogative and sovereignty of interpretation over the arts and culture in general was of great importance for the Manchu rulers, although none of the other nine Emperors of the Qing dynasty that ruled over China invested as much and paid as much attention to accomplish this goal like Qianlong (Wang 2018).

Much like Emperor Huizong of the Song dynasty Qianlong commissioned catalogues of his collections, among which the *Midian zhulin* 秘殿珠林 and the *Shiqu baoji* 石渠寶笈, a series of catalogues of the Imperial collection of religious and nonreligious paintings, manuscripts, and calligraphies, counted for the most prodigious of his catalogues. Moreover, we find inventories of mechanical clocks, telescopes, astrolabes, European artworks of enamel and glass, as well as jewels, sacrificial objects, and jades.

As was the case with the Song Imperial collections, ancient bronzes from the Shang and Zhou dynasties all the way to the Tang dynasty were of paramount importance with regard to Qianlong's collecting and cataloguing practices. The *Xiqing gujian* 西清古鑑, published in 1749, was the first of a series of four catalogues, followed by the *Ningshou jiangu* 寧壽鑑古, published in 1779, and the two sequel catalogues *Xiqing xujian jiabian* 西清續鑑甲編 and *Xiqing xujian yibian* 西清續鑑乙編, published in 1794, describing, illustrating, and categorizing more than 4,000 bronzes ranging from wine and food vessels, musical instruments and bells, to coins and mirrors (Yu 2007). Yet in comparison to the catalogues Emperor Huizong had issued some 600 years earlier, Qianlong's catalogues are much larger in scope, but limited to measures and numbers and rather demure descriptions of the objects listed than engaging in extensive descriptions, interpretations, and age determination efforts as can be found in Huizong's catalogues, demonstrating a somewhat lesser extend of antiquarian acumen and devotion to the objects collected.

Although we see a rapid decline in Imperial collecting and antiquarianism from the reign of Qianlong's son Emperor Jiaqing (1796–1820) onwards several private antiquarians and scholars of the time published catalogues of their collections (Bai 2013). Among them were Qian Dian 錢坫 (1744–1806) and his catalogue of bronze objects, the *Shiliu Changletang guqi kuanzhikao* 十六長樂堂古器款識考, published in 1796, and his catalogue of mirrors, the *Huanhua baishi xuanjing ming jilu* 浣花拜石軒鏡銘集錄, published in 1797, as well as Wang Chang 王昶 (1725–1806) and his *Jinshi cuibian* 金石翠編, a catalogue containing 1500 inscriptions from stone stelae and bronzes from the Xia to the Jin dynasty, complete with transcriptions and discussions of the texts. Another expert collector and antiquarian of the day was Ruan Yuan 阮元 (1764–1849), who published his vast study collections of bronze inscriptions in his *Jiguzhai zhongding yiqi kuanzhi* 積古齋鐘鼎彝器款識 in 1804 together with a comprehensive preface. In his catalogue Ruan Yuan gives an account of the history of

bronze collecting and research and provides illustrations of the objects and their respective inscriptions, all in chronological order and grouped according to a classification system based on object typologies. Moreover, he edited and published the *Huang Qing jingjie* 皇清经解 (1829), an anthology of Imperial erudition in "evidential" (kaozheng) learning and scholarship.

Likewise, Cao Zaikui 曹載奎 (1810–1839), a young and enthusiastic *kaozheng* scholar, antiquarian, and collector published his private collection of bronzes in the *Huaimi Shanfang jijintu* 懷米山房吉金圖 in 1839, together with measures, drawings of the objects, and transcriptions of texts.

One of the last and most prolific antiquarian scholars of Imperial China was artist, scholar-official, and collector Wu Dacheng 吴大澂 (1835–1902). His catalogue of bronzes, the *Kezhai jigu lu* 愙齋集古錄 with inscriptions, typology, and interpretative essays as well as his catalogue of jades, the *Guyu tukao* 古玉圖考 are set at the intersection of traditional antiquarian studies and a more modern approach to artifacts and material culture in general (Demattè 2011).

Overall, scholarly publications on antiquarian studies soared during the last decades of the nineteenth century, paving the way for the rise of western field archaeology and art history at the beginning of the twentieth century (Su 2004).

Key Issues/Current Debates

While antiquarianism and early forms of archaeology during the Song and Qing dynasties have been extensively researched over the last decades, Tang and pre-Tang antiquarianism remains almost completely unstudied. Contrary to the common notion that antiquarian scholarship in China only developed during the Song dynasty (e.g., cf. Visconti 2015), we find literary and historical traces as well as material vestiges of (proto-) antiquarian interests and archaism possibly dating back as early as the Late Shang dynasty (Falkenhausen 2013). Whether the documented preoccupation with and the concern for material relics from the past attests to early forms of antiquarianism, however, remains a desideratum for further study.

Archaeology and Art

James Dixon
Wood Environment and Infrastructure Solutions UK Ltd, London, UK

Introduction

Archaeology has a long history of parallel development with art, and within that relationship, we see a huge range of different nuances. Here, I will focus on evolving connections between the theory and practice of art and that of archaeology. I will, largely, confine discussion to manifestations of "archaeology and art" that have arisen from within archaeology itself. Many artists have taken inspiration from archaeology, its practitioners, and its methods, and although the works produced by these artists are a very important part of the symbiosis of the two fields, there is simply not space for a full review. So, there will be very little discussion here of "art about archaeology," although its existence and volume must be remembered as an essential element of the background to what follows (the term "creative archaeology" encompasses a wider set of practice and theory). It is, of course, not easy to enact such a split. In some cases, specific art works referencing archaeology have inspired archaeological thinking. Here, such works will be discussed. In others, archaeologists have developed creative practices that closely resemble or are intentionally described as art works and these too will be included. Lastly, and perhaps most worthy of fore mention here, outside of the Western scholarly tradition, the relationship between archaeology and art is rather different because archaeology and art themselves can be conceived in different ways. I have opted here to discuss this in the International Perspectives section below, while the main discussion will focus on what "archaeology and art" looks like to me, close up, as a European archaeologist, and its manifestations within the discipline of archaeology.

Suffice it to say that although a particular direction has been taken here, there is a wider world of "archaeology and art" in which the definitions and divisions used here do not matter, and recognizing that openness is essential to creative thinking. The following attempt at ordering recent thought may provide a way in, but is really only an attempt to highlight the wide range of interests and approaches that will and do find a home in "archaeology and art." Ultimately, the idea of "archaeology and art" is a global discussion open to all.

Definition

"Archaeology and art" describes a wide-ranging body of theory and practice addressing the ways in which different engagements with art – principally with artistic practice – can help to create new

ways of thinking archaeologically about the world, its histories, and its futures. It is, at its best, an open-ended field bringing together a wide variety of scholars and practitioners who place collaboration, creativity, and experimentation centrally in their work. Many key "archaeology and art" projects feature artists and archaeologists working together to combine, or to contrast, their approaches to understanding the contemporary world. For clarity here, a distinction is drawn between "archaeology and art" and "archaeology of art," although the two will necessarily overlap, for instance, in the excavation of Francis Bacon's Dublin studio in 1998 (O'Connor 2014) which has gone on to make substantial contributions to both. Where the "archaeology of art" may be more ordinarily taken to mean the occurrence of art objects as a subject of archaeological analysis, "archaeology and art," as the "and" suggests, is usually an effort to suspend objective archaeological analysis and examine the results of collaborative engagement, whether explicitly working with artists or seeking to use artistic histories, theory, and practice in ways that go beyond simple appropriation. As such, "archaeology and art" finds itself more readily engaged with contemporary art (or perhaps, more specifically, with art post-dating the advent of Surrealism), although the two disciplines enjoy a long-shared trajectory of interrelation. From antiquarian representations of their contemporary archaeological worlds, through the interrelation of artists, ethnography, and museums and their role in the development of archaeology as a social science from the late nineteenth into the mid-twentieth century, to the almost identical funding structures imposed on (certain parts of) the two in the public realm of the late twentieth century, archaeology and art have rarely been easily separable.

Historical Background

Early antiquarian depictions of historical and archaeological sites in more artistic than scientific ways will be well known. From William Camden onward, the investigation and description of ancient sites and landscapes went alongside visual representations that sought often to depict those archaeological remains, their investigation, and their landscape context. This tradition perhaps reached its apotheosis in *Our Ancient Monuments*, an outcome of work to establish the first national heritage list in England by Pitt-Rivers in the 1880s. Here, photographs and scientific archaeological drawings of sites are joined by watercolor depictions by W.S. Tomkin, some in a broadly Arts and Crafts style that works to connect not just archaeology and art but developing archaeological theory and practice with a (then) contemporary artistic movement.

In the early twentieth century, notably in Europe, a particular interrelation developed between art, ethnography, and museums that gives us, perhaps, the origin of archaeology as a social science in the contemporary sense and the beginnings of the relationship between archaeology and art that exists today. With new forms of art developing through the late nineteenth and early twentieth centuries, including but not limited to Surrealism, that put greater emphasis on the daily lives of people, ideas of psychoanalysis began to influence art and ideas of "inner minds" and "the subconscious" became an accepted and regular artistic subject. Many artists undertook early ethnographic excursions, a coincidence of their quests to discover the nature and manifestations of "primitive" or "savage" minds and their (for many at least) ability to self-fund expeditions. The result, combined with contemporary developing theory in anthropology, was ideas connecting the subconscious mind, human society, and material culture in such a way as to have a direct impact on early ethnographic museum displays (Kelly 2007). Although archaeology has a longer history than this, it is perhaps at this point that we see the emergence of that part of archaeology that is an academic social science.

In much of the Western world at least, neoliberal politics in the second half of the twentieth century has led to private sector concerns dictating much of the development of the built environment. In the United Kingdom, this combined with a particular kind of cultural aspiration promoted by Margaret Thatcher's Conservative government

in the 1980s (but echoed elsewhere in the world) to create a situation wherein private finance led development directed in part by a body of guidance known as the PPGs (Planning Policy Guidance). These were influential in the development in the United Kingdom of private-sector archaeology, but also promoted green space, playgrounds, art and more, to be created alongside development. Thus we see, and are still very much within, a world where archaeology and art both exist politically and in legislation as aspirations for responsible, sustainable development, both as mitigation and as tangible narratives for changing landscapes.

The three key aspects of the history of archaeology and art briefly presented here do not necessarily run into each other as a chronology might but instead give three different trajectories of that relationship to bear in mind. They all manifest in different ways in the contemporary world and in academic thinking. However, those trajectories – visualization, theorization, legislation – are worth keeping in mind.

Key Issues/Current Debates

At their best, archaeology and art come together in a spirit of collaboration and experimentation. The full range of expressions of that relationship at one level work together to provide a body of work that enables creativity within archaeology, whether in practice or in theory. There are, however, a few themes worth highlighting for their specific contributions to the wider field.

Archaeological Theory and Art

Perhaps the strongest central theme in archaeology and art is the bringing together of aspects of the two disciplines to drive archaeological theory and practice forward. Colin Renfrew, in 2003, wrote of the potential for archaeological engagement with contemporary art to change the way we understand the past. In *Figuring It Out: The Parallel Visions of Archaeologist and Artists*, Renfrew highlights a similarity in how practitioners of the two disciplines think about the connections between people, things, and landscapes, going further to draw an analogy between the visitor to an art gallery, or viewer of a sculpture, and an archaeologist uncovering an artifact for the first time. But this is more than an analogy, he writes, their tasks, coming to understanding of the world through a primary encounter with the result of a creative moment, are the same. Renfrew takes his discussion beyond representation and visualization to encouraging an understanding of artistic process as a means to better understanding human creativity in the archaeological past.

"Archaeology and art" features prominently in *After Modernity*, Rodney Harrison and John Schofield's 2010 work on archaeological approaches to the contemporary past. As part of a wider chapter on working between disciplines, they highlight three relationships between archaeology and art: "art as an archaeological record (or the archaeology of art), archaeological investigation as performance (or archaeology as art), and art as interpretation, narrative and characterization (or art as archaeology)." Their outline works well and has proven influential in much recent writing and presentation on archaeology and art. It does not necessarily describe an equal relationship between the two disciplines, with art perhaps being elevated to a position of understanding to which archaeology should aspire or attempt to emulate (rather than a true collaboration as equals). Despite this minor quibble, *After Modernity* remains the most useful widely available work that discusses archaeology and art within the body of a wider discipline of archaeological thought.

Ian Russell and Andrew Cochrane's *Art and Archaeology: Collaborations, Conversations, Criticisms* (Russell and Cochrane 2014) focuses on archaeology and art coming together in practice and primary research, bringing together a number of practitioners for whom direct engagement with art is central to their thinking. The book, and the essays it contains, stresses the importance of creative collaboration, "archaeology and art" through doing. The work is notable for its inclusion of a number of "creative archaeologists," archaeologists (of different kinds) who regularly build creative expression into their archaeological practice. As such, it stands as

something of a call to action for archaeologists to let themselves be inspired by art and to let that inspiration take their archaeology to new places without necessarily worrying about where those places are or how that might be critiqued.

In 2010, the exhibition *Unearthed* at the Sainsbury Centre for the Study of Japanese Arts and Cultures saw a collaboration between archaeologists and artists use Japanese Jōmon dogū to investigate thematically the potential for archaeology and art to influence each other at the level of interpretation (Bailey et al. 2010).

Archaeologies of Art/Art About Archaeology

Although, as stated above, archaeology *of* art is a different thing to "archaeology and art" as presented here, and although I have restricted myself to discussion of that relationship as it appears within archaeology, it is worth making mention of a few key projects that have worked between the two disciplines. The following stand out for both their innovative approaches to material, whether the impetus comes from archaeology or art, and for their regular occurrence in archaeological writing on art.

Tate Thames Dig by Mark Dion saw the artist, with volunteers, collect material from the Thames Foreshore adjacent to the two London Tate sites. Material was then sorted and classified. The work was first shown as part of the *Art Now* series at Tate Modern between 1999 and 2000 and thereafter entered Tate's collection. Objects collected as part of the project sit in a large mahogany cabinet sorted into various categories, but with no further interpretation. The work avoids chronological ordering of the objects which are presented grouped by broad types (pottery, metal). The viewer is invited to create their own interpretation of the objects seen and their interrelation. Cole and Dion's 1999 book *Archaeology* focuses on the work and other of his works that address similarly archaeological themes. The book includes an essay by Colin Renfrew covering themes later revisited in *Figuring It Out*.

In 1998, a team of archaeologists and conservators excavated Francis Bacon's studio at 7 Reece Mews in London in advance of its being dismantled and installed in Dublin City Gallery The Hugh Lane between 1998 and 2001. As well as the archaeological understanding of the space and its contents created by the project, the work also sought to investigate the connections between artistic and archaeological practices. It inspired a number of written pieces and a plenary session at the World Archaeological Congress in Dublin in 2008.

Journalist, artist, and archaeologist Christine Finn has created a number of projects that work between archaeology and art, but of particular interest is the series *Leave-Home-Stay* in which she addressed, through both archaeology and art (and reportage), the process of dealing with the house she inherited from her parents. The series has involved an excavation, open days, exhibitions of artifacts, and writing on the subject and brings together a wide spread of approaches to the space, from the architectural-historical to the intimate and difficult personal attachment to the house as a home (Finn 2014, 2017).

Performance

It is worth making particular mention of the relationship between archaeology and performance. The archaeological interest in art has most often been interested in sculpture, photography, and film. We see a clear concern with performativity although this is often when, as discussed by Harrison and Schofield, an art work has included a conscious recording and presentation of a process of investigation; archaeological investigation as performance. Performance itself has seen less engagement from archaeologists. Mike Pearson and Michael Shanks' *Theatre/Archaeology* (Pearson and Shanks 2001) discussed this issue, seeking to take the connection between archaeology and performance "beyond the theatrical paradigm," an aspiration roughly equivalent to the move past performativity mentioned above. Mike Pearson has produced further work in this area, and *In Comes I* (Pearson 2007) and *Marking Time* (Pearson 2013) are both exemplary "archaeology and art" although published as part of a Performance Studies list.

Performance differs from other visual media in its ephemerality and temporary nature. It is, perhaps, harder to engage with for archaeologists because it relies on presence at the time of performance (although performances are recorded and "performance re-enactments" take place). Despite this, working with live performance is essential for understanding space and duration, not least for thinking about archaeology; not casting it as a performance, but understanding it as a durational act in the present moment.

Art-Archaeology

Lastly here, we can step away from the "monolith" approach to archaeology and art, the way I have presented here as start points a number of key texts and works taken from a vast body of available work, and acknowledge a messier world of archaeology and art that is going on on a daily basis around the world. Here, "archaeology and art" (or art-archaeology, or art/archaeology, or artaeology, or creative archaeology) exists more as ongoing practical experimentation between archaeology and art. The results may be presented or published, or they may equally validly not be, but connecting everyone working in this area, which includes all of the authors already mentioned, is the desire to allow archaeological practice to be affected and changed by experimentation with art, whether this happens at the level of general creative inspiration or through specific collaboration.

In Europe, much of this kind of experimentation takes place under the umbrella of contemporary archaeology and much has been presented at the various conferences of the *Contemporary and Historical Archaeology in Theory* (CHAT) group since its inception in 2003. Common at CHAT conferences are approaches to archaeology that are intentionally experimental and the extension of this to artistically inspired experimentation (or collaboration) has proven to be an easy one. Art is now regularly recognized among the conference's sub-themes. The result is a kind of archaeology that while not quite fully anti-disciplinary does intentionally blur the boundaries of what archaeology can be and do.

Projects that demonstrate this aspect of "archaeology and art" include the *Papay Gyro Nights* art festival in 2013. This saw archaeologists Antonia Thomas and Daniel Lee undertake an archaeological residency at the festival, bringing creative archaeological practice to Papa Westray in Orkney (Thomas and Lee 2017). Also of interest is the new creative engagement journal *Epoiesen* edited by Shawn Graham, which is beginning to showcase interesting artistically inspired contemporary archaeology including *en-counter-maps* by Gísli Pálsson and Oscar Aldred (Pálsson and Aldred 2017). Between 2007 and 2009, the group Artists in Archaeology (later Art + Archaeology), led by Helen Wickstead, produced a series of artistic residencies alongside the *Stonehenge Riverside Project*, primarily to investigate the archaeological process through art, but also inspiring a number of other creative archaeological outcomes for individual participants (Wickstead 2008, 2014). Archaeologist Carolyn White's ongoing collaboration with photographer and philosopher Steven Seidenberg, including *The Archaeology of Artists' Studios*, has focused on the potential for interdisciplinarity to change how archaeology and art can think differently about space (Seidenberg and White (n.d.); White and Seidenberg 2017). James Dixon has produced a series of projects using artistically inspired practices in public archaeology to differently understand how we might approach local places and sites, and live in or develop them accordingly (Dixon 2017). Ursula Frederick brings her artistic background to contemporary archaeology, both in expanding the range of types of site that might be of archaeological interest and understanding them in ways that need an expanded, refined archaeology, but also in creative experimentation with archaeological recording to produce an allied archaeological-artistic record of sites (Frederick 2014).

I have presented a rather unequal relationship between archaeology and art. This is intentional. The bringing together of archaeology and art, whether through collaboration, or to produce art works, or to produce archaeological products, happens in more ways than can be covered here.

It happens in more complicated ways than will benefit from the simple explanations I have provided. I have chosen to focus on manifestations of the close relationship between archaeology and art within archaeological discourse and publishing and as such have intentionally ignored more than half of what the wider archaeology and art world might be reasonably considered to be.

But, I repeat, if "archaeology and art" is a thing, it is a thing about openness and experimentation, and will mean a different thing to every person who engages, if they are thinking creatively beyond the referencing of texts.

International Perspectives

Archaeology and art exist, of course, across the world. The relationship between the two is highly variable although outside Europe and the USA one seems more likely to encounter archaeologies of art or art about archaeology than the kind of collaborative, experimental work presented here, although it does exist. There are many reasons for this, not least that the relationship between art and the daily lives of people is equally variable wherever we go, and different art forms dominate different places.

We should recognize that the blurring of disciplinary boundaries is an aspiration that principally arises from positions of security. The freedom to self-ascribe permission to disregard established practices should not be taken for granted. Of course, in most cases, this kind of experimentation is undertaken from a position of respect for the disciplines involved where proper knowledge of the two is recognized as a necessary precursor to pushing at the edges. Elsewhere, the same respect and knowledge may result in intentionally not-experimenting.

Global "archaeology and art" has benefitted in recent years from prominent placement at international conferences, notably the World Archaeological Congress (WAC). At WAC 6 in Dublin, a strong archaeology and art theme ran through the conference, inspired by the tenth anniversary of the excavation of the Francis Bacon studio. The aforementioned volume edited by Ian Russell and Andrew Cochrane (Russell and Cochrane 2014) arose partly from this conference, as well as their earlier collaborations around archaeology, art, and visualization, for instance, as presented at the CHAT conference in Bristol in 2006.

Archaeology and art was again a central theme at WAC 8 in Kyoto in 2016. Here, a number of sessions in the area, including art-archaeology and archaeology of art, ran alongside two exhibitions, *Art and Archaeology: The Silent Voices of Materials and Soil* (cur. Sahoko Aki, Masakage Murano, Oki Nakamura, and Toshio Matsui) (Museum of Kyoto 2016) at Museum of Kyoto, and *Garden of Fragments* (cur. Sahoko Aki and Peter Matthews) at Ryosokuin temple. There were also a number of other events bringing archaeology and art together. The particular Japanese perspective on archaeology and art presented at WAC 8, and through the preceding 2 years of work by the Kyoto Art and Archaeology Forum, has shown a relationship between the two much more centered on aesthetics. The Japanese context however leans toward a role of aesthetic thinking in daily life that may not, perhaps, exist so explicitly elsewhere and which will provide a rich source of inspiration for non-Japanese archaeologists in the future.

Future Directions

The key future direction for "archaeology and art" is to do more of the same. As has been stated throughout here, "archaeology and art" as a subfield of archaeology is intentionally open, collaborative, creative, and experimental. It benefits from not having an overt agenda. More creative archaeologists from around the world should meet and work together. Ultimately, "archaeology and art" should aim toward ways of doing archaeology and thinking archaeologically that create better understanding of people, places, and things, and that will happen best if it works to become more inclusive of all takes on what "archaeology" and "art" (and "and") can mean.

Archaeology and Colonialism

A. José Farrujia de la Rosa
Universidad de La Laguna, Santa Cruz de Tenerife, Spain

Introduction

Colonialism and culture contact have become hot topics in archaeology. Colonialism has been implicated frequently as one of the most significant forces in world history, and the current global situation is, to a large extent, the product of a long and complex history of colonial encounters. Indeed, according to Frank and Gills (2000) or Chris Gosden (2004), one could claim with some justification that the past 5000 years of human history have witnessed an unending series of colonial encounters and attempts at imperial expansion. At the same time, archaeology can trace the material dimensions of colonialism, and, therefore, archaeology and material culture studies let us understand the range of forms in which colonialism is manifest in both modern and ancient human societies (Given and Knapp 2003; Gosden 2004; Farrujia 2014).

It has been estimated (Frank and Gills 2000; Stein 2005) that, by the early decades of the twentieth century, one half of the surface of the earth's continents was under some form of colonial domination and about two fifths of the population of the world (more than 600 million people) were living under colonial rule. Other regions (such as Latin America) had suffered long periods of transformative colonial domination in previous centuries. Moreover, despite the dramatic collapse of the major European colonial empires in the face of widespread popular resistance movements during the last half of the twentieth century – giving rise to the recent popularity of the term "postcolonial" to describe the current world situation – colonialism is still alive and well. Moreover, several current states that are dominated by populations resulting from earlier episodes of settler colonialism (e.g., the United States, Canada, Australia, New Zealand, or the Canary Islands) are hardly

postcolonial from the standpoint of the descendents of the indigenous inhabitants.

The development and regional manifestations of the modern capitalist "world system," in both its colonial and "postcolonial" guises, have become an increasingly central focus of research by historians, sociocultural anthropologists, and archaeologists during the past few decades.

Definition

Colonialism is a concept tied to the last 5000 years and not just a post-Columbian concept. According to Gosden (2004: 153), colonialism is not many things, but just one. Colonialism is a process by which things shape people rather than the reverse. Colonialism exists where material culture moves people, both culturally and physically, leading them to expand geographically, to accept new material forms and to set up power structures around a desire for material culture. There are different types of colonialism:

- A colonialism that is ruled from a center (metropole) that exploits other's resources through economic and military power and establishes colonies or administrative, indirect rule (the British Empire, Roman Empire, etc.).
- Other colonial activities are tied to migrations and settlement that are not regular colonies but have to do with the power balance among various cultural groups which can result in hybridizations but can also result in that one group take over the recourses on the expense of the other group.
- A third group of colonialism is when one group tries to eradicate or marginalize indigenous people (North America, Australia, New Zealand, the Canary Islands, etc.).

Historical Background

The above classification is broad in scope and takes into consideration the work of world system theorists, in particular Wallerstein (1974, 1980) and Frank and Gills (2000). "Colonialism within a shared cultural milieu" would be the term used by Gosden (2004) to describe the earliest (and perhaps most controversial in terms of their acceptance as colonial contexts) colonial forms, such as those that existed from Mesopotamia to the Greeks and among the Aztecs, Incas, Chinese, and Tongans. This form of colonialism is characterized by colonial relations between state and nonstate polities, where power is manifest in forms that operate within norms of social behavior and where the limits of colonization are controlled not by military power but by the area over which a particular culture is shared or spread. Colonial "middle grounds" are exemplified by the peripheries of the Greek colonies and the Roman Empire and early modern contacts with indigenous peoples in North America, Africa, India, and the Pacific. These forms of colonialism are characterized by experimentation and creativity and consist of accommodation on the part of both indigenes and colonists and the development of regularized social relations. *Terra nullius* colonialism, as evidenced by the major settler societies of Australia, New Zealand, North America, and Russia from the mid-eighteenth century but also by the Mongols and Spanish in Peru and Mexico and in the Canary Islands too, is characterized by extreme violence, mass appropriation of land, and the spread of disease which enables the destruction of existing forms of social relations. Active resistance to colonial forms which allow indigenous cultural continuity often exists in such circumstances. *Terra nullius* colonialism is differentiated from the other forms by the existence of relatively fixed categories of difference, whereas in middle-ground colonialism, new categories of difference are often created by cross-cultural encounters, and in the case of colonialism in a shared cultural milieu, no such categories of difference may exist.

Key Issues/Current Debates

There are several approaches that have contributed to a renewed interest on the archaeology of colonialism from within archaeology on issues of contemporary relevance to both indigenous and

nonindigenous peoples in settler societies and to the development of a truly global perspective on world history (Lyons and Papadopoulos 2002), culture contact (Fagan 1998; Torrence and Clarke 2000; Murray 2004; Silliman 2005; Farrujia 2014), or the historical archaeology of indigenous peoples (Murray 1996; Harrison and Williamson 2002; Paterson 2003; Byrne 2003).

The current debates about archaeology and colonialism are influenced by postcolonial theory. This is the case, for example, of one of the most influential approaches, Gosden's work (2004), particularly in terms of understanding the intellectual traditions that underlie the concept of colonialism and how nineteenth-century views of colonialism influence strongly the way in which it has been studied by academics. But there are several other archaeologists that have currently worked in the field of culture contact (Torrence and Clarke 2000; Gosden and Knowles 2001; Farrujia 2014), strongly influenced by the work of Edward Said (1979) and Nicholas Thomas (1991, 1994).

Other authors, such as Given (2004), are interested in the lived experience of colonialism for those on the receiving end of colonial regimes, a "bottom-up" approach to understanding the materiality of the colonial project. Given's focus is narrower than Gosden, both geographically and in terms of the forms of colonialism with which he deals. Most examples are drawn from Turkey and Cyprus, although he also cites material from the Old Kingdom of Egypt, Nazi Germany, and nineteenth-century Scotland. He is most interested in those particular forms of colonialism which express themselves through taxation and the material manifestations of empire.

Regarding postcolonial archaeology, studies have indisputably produced a richer, more complex, and nuanced vision of colonial processes (Gosden 2004; Lyons and Papadopoulos 2002; Stein 2005). However, despite that cultural hegemony and economic exploitation are not two different or even opposed interpretations of colonial power but they should rather be seen as two sides of the same coin, the truth is that the political side of colonialism tends to be ignored in current studies of the phenomenon (Gosden and Knowles 2001; González-Ruibal 2010). This might be dangerous; by stressing fluid encounters, negotiation, hybridity, consumption, agency, and creative appropriation (Dietler 2010), we neglect the crudest side of colonialism – politics, including political economy, asymmetrical power relations, massacres, looting, disease, impoverishment, unequal wars, heavy taxes, and genocide. Surely, these are not always relevant, especially in ancient examples (e.g., Dietler 2010). Yet by overlooking politics, we run the risk of depriving the people without history of the history that hurts, the experience of daily humiliation and abuse by foreign masters (Given 2004: 163).

This means that postcolonialism is not just about attempting to reveal, recognize, and heal the problems of the past, but it is also about trying to move toward a new future in which emotions of belonging can be strongly and proudly felt at a local level but also effectively mobilized at a more global level to gain recognition and the resources necessary for local cultural forms to thrive. It can, for example, comprise of an archaeology where indigenous people use archaeology to tell their own stories and in relations to land rights. In some areas the complex current political situation can make archaeology and archaeological remains political, and the one or the other cultural, political, or religious group, for example, tries to destroy or degrade the other group's iconic monuments. According to Gosden (2012: 263), we know we are not yet postcolonial but carry the hope that we can become so.

International Perspectives

In the specific case of Europe, modern European colonialism has affected the whole world, and its legacy is overwhelming today. It would be enough to review the works and thoughts of European archaeologists on other continents. However, since Said's *Orientalism* (1979), we know that colonial categories not only constructed an image of the other but were also fundamental in shaping European identity, science, and politics. Thus, there is a particular relationship between colonialism and European archaeology that has

already been explored (González-Ruibal 2010; Farrujia 2014).

In the Canary Islands, an archipelago located on the Atlantic Ocean, just 100 km (62 miles) off the southern coast of Morocco, the colonial past has had a clear influence on the development and evolution of Canarian archaeology, also shaping archaeological heritage management in the islands. Consequently, the study of the interrelations between the colonial past and Canarian archaeological studies may be considered relevant to the subject of archaeology in an international context for three reasons. First of all, it provides an almost unique opportunity for uncovering the history of archaeology within the margins of Europe (in fact, in an African region) and exploring colonial and foreign influences. In many ways it is a mirror of archaeological mainstreams and an exercise in (re)thinking the aim and status of present-day archaeology.

Second, it is an exceptional opportunity for revealing the "weight of tradition" by presenting a form of archaeological heritage management that has interesting oppositions, namely, the European/monumental heritage (Castilian monuments and buildings) versus the African/nonmonumental heritage (Amazigh or ancient Canarian sites). In this sense, given the monumental, lavish, and artistic nature of the antiquities of mainland Spain (Iberian, Roman, Visigoth, and Arab, to give just a few examples), the archaeology of the Canary Islands is very different. The material culture of the indigenous settlements in the archipelago is characterized by greater simplicity and sobriety, handmade ceramic vessels, which are sparsely decorated, lithic tools made essentially from obsidian or basalt, the bone industry, very few metal objects, the predominance of cave dwellings, etc.

The third important reason is that the situation in the Canary Islands provides an opportunity to study the role played by colonialism in archaeological heritage management. Many books have appeared recently on European archaeological heritage management (Cleere 1984, 2000; Willems 2007; Smith and Waterton 2009; Mauch and Smith 2010) and several on colonialism and archaeology (Lyons and Papadopoulos 2002; Gosden 2004; Dietler 2010; Burchac et al. 2010; Carlson and McHalsie 2010; Lydon and Rizvi 2010), but the possibility of researching both within Europe, in the Canary Islands, is certainly an extraordinary phenomenon, even taking the following fact into account: in the Canary Islands, there is no indigenous archaeology – i.e., archaeology produced by and for indigenous people – since the conquest and colonization of the Canarian archipelago led to the gradual disappearance of the precolonial societies (Farrujia 2014). However, the European colonial discourse that influenced archaeology in other indigenous contexts (Australia, Africa, etc.) is also evident in the Canary Islands. As Ireland (2010) has pointed out, indigenous and nonindigenous communities are all engaged in the active "use" of the colonial archaeological heritage as much as any other forms of tangible or intangible heritage.

Future Directions

Archaeologists have a good deal to gain from theoretical insights generated by other disciplines, but they also have much to contribute to the field as a whole by virtue of both their privileged access to a comparative perspective on the deep history of precapitalist colonial encounters and the complementary kinds of evidence they can bring to bear on the study of the historical process of modern colonialism. In fact, the study of colonial encounters is a field with unusually rich potential for mutually beneficial collaboration between archaeologists and historical anthropologists. As Gosden notes (2004: 6), "colonialism is the major cultural fact of the last 500 years, and to some extent of the last 5000 years, although it is said we now live in a postcolonial world... we are still wrestling with the economic, intellectual and social consequences... by looking at the varying forms power can take we can learn much about the past and unlearn much about the present." In this sense, the future directions of the studies on archaeology and colonialism should deal with the general understanding of the highly variable

nature, structure, and effects of colonialism. Also, the distinctive potential contributions and methodological strategies of archaeological research on this issue should be examined, and, of course, a comparative perspective (in both spatial and temporal terms) on processes of social and cultural transformation associated with colonialism should be furnished.

Regarding postcolonialism, historians of archaeology do not need a postcolonial viewpoint to recognize the continuing effects of colonialism and imperialism over the practice of archaeology. Indeed, the recognition that most archaeological agendas have been affected to some degree by Western imperialism has been carried out without reference to postcolonial theory. During the last two decades, historians have traced the effects of Western imperialism over archaeology, have depicted how colonialism determined which questions were and were not investigated, and have demonstrated that some archaeological evidence has been systematically misinterpreted to offer a historical justification for colonialist interests. These investigations have been undertaken without reference to postcolonial studies. However, postcolonial studies offer a wide variety of theoretical positions, ideas, and categories that can be useful to elucidate the nature and impact of colonial powers and their effects on archaeological practice. The field provides a set of critical terms that are helpful in unraveling the complex nature of relationships between colonialism and science. Terms such as "colonial discourse," "appropriation," "hegemony," and "authenticity," for instance, have generated extensive discussions in parallel fields such as anthropology and history and can be similarly used both in archaeology and in the history of archaeology. The use of elaborate theoretical frameworks such as postcolonial studies can assist historians to overcome a central problem in the new history of archaeology: if archaeology is to be understood in terms of its social and political context, then historians of archaeology must define "context" more precisely, and they have to specify in which ways the social, political, and cultural environment has marked archaeological agendas, as it has been argued by Moro (2006) or González-Ruibal (2010). To do this, the history of archaeology should be informed by debates and discussions developed in other fields, like postcolonial studies. This interdisciplinary approach can provide historians with critical tools to better understand the assumptions within the discipline.

Introduction

The Republic of Kiribati [pronounced: Ki-ri-bass] consists of a group of 32 low lying atolls and reef islands and one raised coral island, Banaba (Ocean Island), situated at the interface of Micronesian and Polynesian cultures in Remote Oceania and part of the Fiji-Tuvalu-Kiribati chain (Fischer 2013: 28). With 3.5 million km^2 of marine jurisdiction and only 800 km^2 of land, this generally dry equatorial country represents one of the most isolated and infertile parts of the world. The name Kiribati is an appropriation of the colonial name Gilbert Islands, with the local name for the archipelago being *Tungaru* and their inhabitants referred to as *I-Tungaru* (or *I-Kiribati*). Kiribati, also previously known as the Kingsmill Islands, straddles the equator and extends over 400 miles north to south. The 112,000-strong island nation of *I-Kiribati* is divided administratively into three main groups of islands (Fig. 1): the Gilbert Islands, currently the most populated, with half of the nation's population inhabiting the capital of South Tarawa alone; the Phoenix Islands (the first UNESCO World Heritage site in the country in 2010, and remains the second largest designated Marine Protected Area in the world, whc.unesco.org), which are largely uninhabited; and the Line Islands, situated on the dateline border, and – similar to the Phoenix group – were found to be uninhabited by the first Europeans (the "mystery islands"; Thomas 2003: 4) (see Fig. 1). The *I-Kiribati* are relatively homogenous linguistically and their

language, also known as Gilbertese, is a Micronesian tongue with some Polynesian borrowings. The language is distinct from neighboring Tuvalu and Marshall Islands, all of which belong to the Austronesian language family.

Cultural links between Micronesian and Polynesian cultures, especially with Samoa, are strong, with creation myths referring to ancient back-and-forth migrations between the two nations (MacDonald 2001: 3), and a recent migration from Samoa to Kiribati some 500 years ago, around fourteenth century CE, often explained as a "return of Kiribati Islanders" (Kirion and Karaiti 1979: 10). It is believed that the Samoans introduced the use of *manaeba* (e.g., communal meeting house), initially on the island of Beru, influencing the development of specific sociocultural norms (Petersen 2009: 216; Fischer 2013: 62–63, after Gheuens 2017). Southern islands of the Gilbert chain were influenced by the Samoans with the northern islands remaining independent up until their colonization by the south in the seventeenth century. This led to two centuries of struggle and resistance by traditional chiefs and powerful landowners who opposed the new, southern, sociopolitical system run by the council of elders.

Early contact with Europeans was usually brief due to the scarcity of resources that Kiribati could offer, although Darwin notably visited the Phoenix islands between 1831 and 1836 to study the creation of low lying atolls (Onorio 1979: 29). Longer-term interaction, often initially fractious, started in the early nineteenth century, with whalers visiting the islands regularly from the 1830s and initiating early trade in iron hoops and tobacco in exchange for food and women. In these early days, *I-Kiribati* men were often employed on whaling ships but since the 1860s labor trade was introduced in Kiribati with "recruitment" (early on as kidnapping and evolving eventually to volunteering) to work on plantations in Fiji (Onorio 1979: 34–37). No archaeological investigations to date have focused on this period (fourteenth to nineteenth century). Kiribati gained independence in 1979 after being a British protectorate from 1892 and a British colony from 1916.

The archaeology of Kiribati can be written into a methodological framework of Islands Archaeology (e.g., Rainbird 2007), although different aspects of archaeological and cultural heritage in these archipelagoes can be studied using diverse archaeological methods and techniques. A long history of anthropological research in Micronesia and Polynesia – going back to the times of first contact with missionaries, traders, whalers, and travelers – enabled the development of a so-called social archaeology (Rainbird 2004).

Because of their small size, limited and fluctuating resources, and relative isolation, low-lying

atolls are often depicted as marginal habitats for human settlement. While some communities did not endure (Anderson et al. 2000; Di Piazza and Pearthree 2001a), a remarkable number of atolls (and other small islands) continued to support human populations for centuries, indicating a long history of resilience to environmental variability. Stratified cultural deposits tend to be concentrated where people live today (i.e., on the larger islets), although later settlements expanded from the center toward the lagoon, which was facilitated by land progradation (Thomas 2014; Weisler 1999, 2001).

Historical Background: Archaeology

Early research on the only raised coral island of Kiribati – Banaba – confirmed the dating of an interior village to the late prehistoric or an early historic period (Lampert 1968, see also Grimble 1989 for other sites and Thomas 1999: 58–62 for a review). Pioneering archaeological research on atolls in Kiribati was conducted by Richard Shutler who in 1969 visited Tarawa, Abemama, Butaritari, and Makin and collected a few shell adzes (Di Piazza 1998). The first archaeological excavations followed in 1983, undertaken by a Japanese team (who collaborated with Shutler on the Caroline Islands in the 1970s) at the Utiroa Site on Makin, and later on North Tarawa. Oral traditions from Makin propose that there used to be settlements located on both sides adjacent to an island passage that was subsequently filled by heavy sedimentation and the wave action. Utiroa was dated (although not without contention) to 1400 BP (Takayama and Takasugi 1985) and resulted in the discovery of a deeply stratified cultural deposit of approximately 3.5 m (Takayama and Takasugi 1987, 1988). Later excavations by the team at the site of Nukantekainga on North Tarawa were limited in depth, but artifacts confirmed parallels with Polynesia especially through the findings of dog and porpoise tooth pendants (Takayama et al. 1990). This early research specifically focused on establishing a chronology for the first occupation of the atolls and the establishment of external connections with other parts of Micronesia and Polynesia.

The French archaeologist, Anne Di Piazza (1998, 1999a, b), carried out research on Nikunau in the southern Gilberts, which yielded the earliest reliably-dated deposits for the initial occupation of Kiribati. These dates are consistent with some of the earliest dates in Eastern Micronesia, including the Marshall Islands to the north, at about 2000 years B.P.

Since the mid-1990s, ethnographic and ethnoarchaeological research, supplemented by archaeological excavations and historical ecological data collection, was undertaken by Thomas on selected atolls in the Gilbert Islands (2001, 2007a, b, 2009). Radiocarbon dates on wood charcoal derived from swamp taro pit mounds on North Tarawa showed evidence of human activity at about 1800 BP. Other radiocarbon dates, some associated with buried A horizons, suggested land clearance between the third and seventh centuries CE.

Using a regional approach to understand island settlement and abandonment, Di Piazza and Pearthree (2001a) proposed the concepts of "mother communities," "satellites," and "isolates" and concluded that resource scarcity and/or isolation resulting in abandonment were likely explanations for those islands that were relatively inaccessible, small, and/or dry. Some islands appeared never to have been inhabited, perhaps because they were too marginal in terms of water availability or because their fringing reefs prevented effective fishing. "Mother communities" with high rainfall, such as Tabuaeran (Fanning Island), once supported relatively large resident populations supported by a rich agricultural base. These communities periodically exploited nearby satellites (e.g., Kiritimati – Christmas Island) which, despite their drier appearance, were located within an overnight voyage of a richer land and offered attractive faunal resources, especially seabirds and turtles. While the demise of "mother communities" remains problematic, settlement extinction need not be explained solely in terms of environmental crunches. The occurrence of exotic basalt (Di Piazza and Pearthree 2001b, c), together with the abundance of timber for

canoe building, should serve as a reminder that populations were capable at any time of migrating to other archipelagoes.

The "Mystery islands" (Bellwood 1978) of the Phoenix and Line chains, of Polynesian origin, have been studied since the 1920s and 1930s, with archaeological coverage largely limited to describing surface features (Emory 1934). All of these low coral islands were uninhabited when first discovered by Europeans. While building up local chronologies, archaeologists have more recently considered the probable causes for the abandonment of these islands (Anderson 2002; Anderson et al. 2000).

Historical archaeology in Kiribati has not been a particularly popular research avenue to date. The site of the first mission in Kiribati – established on Abaiang Island in 1857 by Reverend Dr Hiram Bingham II – is well known, with one of the later versions of the church in Koinawa (Fig. 2) and a commemorative marker – often mistaken for his tomb – remaining fairly well-preserved and maintained. To our knowledge neither has been recorded archaeologically.

Due to the recent history of archaeological research in Kiribati, the focus continues to be on culture history, especially the establishment of settlement chronologies with maritime, shoreline, and historical archaeology only recently becoming research objectives, including the documentation of submerged and half-submerged World War II features related to the Battle of Tarawa on the islet of Betio (pronounced: Be-soo) and Battle of Makin fought on the island of Butaritari. The mass graves of both soldiers and workers, including Japanese, Korean, and Americans, rusting artillery, ships, tanks, guns, bunkers, and other relicts are still visible on the island of Betio where the battle took place (Fig. 3). A number of groups have been involved in documenting this cultural heritage and some

Archaeology and Cultural Heritage in Kiribati, Fig. 2 Koinawa church on Abaiang in early second decade of 2000 (left) and 2018 (right). Note the deterioration of painted decoration over a short period of time that has been sustained in the tropical area. (Photos: left – F Thomas; right – AM Kotarba-Morley)

Archaeology and Cultural Heritage in Kiribati, Fig. 3 Top: Archival photos from Battle of Tarawa on the islet of Betio. (Source: AP Photo). Bottom: remains of military equipment from World War II on the islet of Betio. (Photos: AM Kotarba-Morley)

historians have collected oral memories of the battle (Thomas from 2007). No coherent archaeological research has been published about World War II relics on Betio to date.

The atoll of Nikumaroro (Gardner Islands) has been the focus of attempts at finding the plane-wreck of the Lockheed L10 Electra that was piloted by the world-famous aviator, Amelia Earhart, who disappeared over the Pacific during her attempt to circumnavigate the globe in July 1937 (King et al. 2004). Survey attempts in the 1940s by Gerald Gallagher, first officer-in-charge of the Phoenix Islands Settlement Scheme – the last colonial expansion of the British Empire – identified a camp, now known as the Seven Site, and a skeleton with an old sextant amongst a few other items. These were shipped to Fiji for an assessment by a colonial doctor, who determined them to be of a European male, but have since been lost.

During the 1940s surveys, a photograph – known as "Bevington Image" – has been taken revealing, what some interpret, as an object similar to landing gear from Electra. Significant research efforts have been expanded to locate the wreck including almost 30 years of research over 12 expeditions carried out on Nikumaroro by The Historic Group for Historic Aircraft Recovery (TIGHAR) as well as a very recent (August 2019) 2-weeks long, multimillion dollars unsuccessful attempt by the Titanic discoverer Robert Ballard (Cohn 2019). The New York Times reported that Ballard's team on Nautilus used multibeam sonar, and deployed a floating autonomous surface vehicle to map shallower areas off the island's shore, as well as four aerial drones for additional inspections of the surrounding reef. During this search they discovered old, 'yet unidentified', shipwreck two hats in the depths, debris from an old shipwreck, and even spotted a

soda can, yet they were unable to locate a single piece of Lockheed Electra that supposedly sunk there in 1937 (Cohn 2019).

TIGHAR team are now entering a new phase of research after locating the notes of the Fiji doctor and having them re-examined by Richard Jantz, director emeritus of the Forensic Anthropology Center at the University of Tennessee, who determined that they belonged in fact to a woman of a statute in 99 percentile probability similar to that of Earthart. No bones have been found at the site of a castaway camp since the 1940s however, but researchers hope that new analyses of 22 soil samples and a female skull from the Museum in Tarawa collected by the team of DNA scientists Hiebert and Kimmerle will shed new light on the possibility of Earthart's existence as a survivor on Nikumaroro .

In general, apart from Ballard's recent search, to date there have been no serious attempts at undertaking underwater archaeological investigations in Kiribati due to the lack of equipment and diving facilities on most of the islands.

Cultural Heritage of Kiribati

The typologization of Cultural Heritage is always an onerous task, yet one that is of importance to future generations of researchers setting out to document the often rapidly vanishing heritage of small islands and Pacific atolls, Kiribati included. Local preservation initiatives have shown what is important to local communities (Thomas and Teaero 2010), and although not exhaustive the list below records a number of cases where heritage assets have been perpetually conserved and maintained by generations of *I-Kiribati.*

Below we propose a typological scheme that takes into consideration (Table 1) archaeological, built and tangible heritage although we do acknowledge that in the Pacific in general, Kiribati included, people do not usually make a strong distinction between tangible and intangible cultural heritage, or even cultural and natural heritage. For the purposes of this chapter we omit intangible aspects of heritage (the "living heritage"), which include traditional knowledge, tools, and crafts connected with seafaring, shipbuilding, ocean fishing, and near-shore trapping, as well as objects such as hair and shell necklaces, tattooing implements, shell ornaments, combs, rope, baskets, and traditional weapons such as famous porcupine fish helmets, pandanus leaves back shields and chestplates, and shark-teeth ritual daggers/swords and wooden clubs. Collected over 130 years, many of these objects are located in the museums around the world with the unique coconut fiber armor found in 'other parts' of Europe 23 museums in the UK, in addition to those in Europe and Oceania. We also exclude from this entry food preservation and preparation technologies as well as oral histories and beliefs, folklore, and arts including myths and cosmologies, indigenous epistemologies, performance arts, especially dancing of which *I-Kiribati* are especially proud, as well as the art of tattooing with its elaborate and unique patterns. While we recognize that these aspects of heritage are of great importance to *I-Kiribati*, these will be discussed in a separate entry.

Key Issues and Current Debates

Culture is a vital link between past, present, and future and on Kiribati encompasses both places and people. However, local residents do not generally regard landscapes as heritage and remain ambivalent about preserving places and sites per se – in a Western sense – rather favoring areas in which particular traditional activities are practiced. On the islands, culture is still firmly rooted in kin and community obligations and therefore the traditional definition of "cultural heritage" in Remote Oceania should ideally be expanded to include traditional forms of knowledge and intangible connection with land, shoreline, and ocean.

I-Kiribati were originally entirely dependent on their maritime resources which also formed the basis for their social identity. However,

Archaeology and Cultural Heritage in Kiribati, Table 1 Types and Elements of Archaeological and Cultural Heritage Sites in Kiribati

Type	Element	Notes
Maritime and coastal cultural landscapes	**Cultural and "transported" landscapes**	The "transported" landscapes (Anderson 1952; Kirch 2017) were a byproduct of colonization events connected with seafaring migration that brought cultivable plants and domestic animals, as well as weeds and commensal animals (such as rats) to the islands. These transported landscapes did not – as some would posit – arrive as a single package, but rather differed significantly across different geographic and cultural regions. Agriculture was often focused upon a single crop of high and rapid carbohydrate production, such as taro (Fitzpatrick 2008), due to the overabundance of dietary protein (e.g., shellfish) (Fig. 4, top left). Giant swamp taro pits are present in most of the inhabited islands and according to radiocarbon dates were already excavated by around 1800 BP (Thomas 2019, personal communication). Although many of these pits are not maintained today, they still represent a living part of the cultural landscapes providing important dietary supplement if not, on some islands, remaining a staple. Local residents do not perceive "landscape" as "heritage" although they recognize the importance of the traditional activities that are performed within the seascape, coastscape, and landscapes, such as fishing, fish trapping, seafaring, and the cultivation of various plants and trees (Fig. 4).
	Aquaculture	These represent a unique type of "land use" in Kiribati and other Pacific islands, developed as a part of risk aversion strategies where placing the larger species of giant clams close to the shoreline may be considered a risk reduction strategy (Fig. 5). It represents a unique and ingenious form of live storage of animal meat and can be seen as one of the hallmarks of the maritime cultural landscape of Kiribati.
	Agroarboreal production, atoll agroforestry	In response to the most severe environmental constraints and greatest population pressures, atoll-dwellers have created the most intensive agroforestry in the entire Pacific, with the greatest relative dominance of trees over non-trees (Latinis 2000). Apart from widespread copra plantations, other cultivated fruit-trees include *papaya*, banana and plantain *cultivars*, the native fig, or te bero (*Ficus tinctoria*), the common fig, or te biku (*Ficus carica*), and the lime (*Citrus aurantiifolia*). More archaeobotanical studies are needed to establish the relative presence of these different species in various periods of the past and to establish the reliance of people upon their crops.

(continued)

Archaeology and Cultural Heritage in Kiribati, Table 1 (continued)

Type	Element	Notes
Pre-European archaeological sites	**Occupation sites, cultivation sites, and shell middens**	Pre-European archaeological sites have been documented on Makin (Takayama 1988; Takayama and Tagasugi 1985, 1987), Abaiang (Thomas 2014), North Tarawa (Takayama et al. 1990; Thomas 2014), Tamana (Takayama et al. 1989), and Nikunau (Di Piazza 1998, 1999a, b) in the Gilberts Group (some artifacts with midden materials, and in other cases, charcoal from giant swamp taro pit mounds, see Fig. 6) (Thomas 1999).
	Ceremonial sites	There have been a small number of sites recorded in the Phoenix Islands mostly associated with *marae* or ceremonial sites of Polynesian origin (Di Piazza and Pearthree 2004) and a study was conducted in Line Islands on Kiritimati and Tabuareran (Di Piazza and Pearthree 2001a).
	Burials (terrestrial and submerged)	We believe that no archaeological excavations of precolonial burials have been carried out thus far on land. However, according to a UNESCO report (Guérin et al. 2010: 53), a number of ancient submerged burial sites have been documented at Bike in Abemama and Kuma in Butaritari. Bike, located 4 h away by sailing canoe from Abemama, is partially inundated and according to legend used to serve as a cemetery. Additionally, a small mound enclosed in mangroves with the burial site of a woman known as Nei Teinaieta said to be located at sea close to Kuma on the island of Butaritari (Guérin et al. 2010: 53).
	Underwater, coastal and maritime sites	*I-Kiribati*, as all Micronesians and Polynesians, are inextricably connected with the ocean. Numerous underwater cultural heritage sites are known from oral histories and legends including, now submerged, traditional settlements, meeting places, burial sites, and ancient fish weirs and traps. Some of the sites are well-known and even documented, while others remain in the domain of local legends (Guérin et al. 2010: 53). One example of such sites is a submerged *mwanaeba* identified based on a number of submerged coral block pillars recorded on Temotu, one of the villages at the end of Nonouti Island. Local divers confirmed seeing pillars arranged as the *mwanaeba* would be with one of the elders of the village confirming that the structure would have once stood on dry land (Guérin et al. 2010: 53).
Colonial and postcolonial archaeological sites and structures	**Colonial buildings**	The first permanent traders who established themselves in the Gilberts were Rendell and Durant who, in 1846, started coconut oil and turtle shell manufacture on the northern – wet – island of Butaritari and then Durant moved south to Makin. There are no visible remains of any of their trading posts today. It is important to note that not all agents were foreigners; a local man Kaiea of Abaiang was also trading with coconut oil – again

(continued)

Archaeology and Cultural Heritage in Kiribati, Table 1 (continued)

Type	Element	Notes
		no archaeological evidence for this trade has been documented to date. The mid 1850s followed with the introduction of Protestant missionaries – some of the buildings and monuments from this time are still visible including Bingham's church on Abaiang. The maintenance of such colonial architecture in the tropics is very challenging (see Fig. 2: the photos from 2014 and 2018) notwithstanding the fact that studying colonial heritage in Oceania always has to be set against ongoing struggles over land, resources, and identity in the region today, encapsulated by the tension between the global and the local (Flexner 2014).
	WWII remains and sites (terrestrial, nearshore and some underwater)	The Islet of Betio was the scene of one of the largest battles of the Pacific Theatre of World War II. Fought in November 1943 as part of Operation *Galvanic* – the US invasion of the Gilberts – this battle witnessed nearly 6400 Japanese, Korean, and American soldiers perish in just 76 h of intense fighting. The American invasion force consisted of 17 aircraft carriers (6 CVs, 5 CVLs, and 6 CVEs), 12 battleships, 8 heavy cruisers, 4 light cruisers, 66 destroyers, and 36 transport ships and a total of about 35,000 troops and was the largest yet assembled in the Pacific. The sheer quantity of monuments and objects left behind by both sides and their current location on beaches of the most densely populated neighborhood in South Tarawa – Betio – make conservation and documental efforts very challenging. Every few years, bodies or a mass grave are identified somewhere in Betio with the most recent 22 Marines repatriated on July 17 2019. While there have been some ad hoc preservation efforts and campaigns by WWII enthusiasts and army veterans, no large-scale coordinated documentation and preservation efforts have been carried out to date. Operations *Galvanic* and *Kourbash* were the code names for the Gilberts campaign – part of "Gilbert and Marshall Islands Campaign." This campaign included the seizure of Tarawa and Butaritari, which was known by US forces as Makin Atoll, and was the site of the Battle of Makin fought from 20 to 23 November 1943 (CMH 1990). A total of six shipwrecks are known to be located in the waters of Kiribati, including a US escort carrier, *Liscome Bay* on Butaritari and two Japanese submarines (Guérin et al. 2010). Due to recent Chinese enterprises exporting metal from Tarawa many local sites are being seriously damaged and looted as source of income (Guérin et al. 2010).

Archaeology and Cultural Heritage in Kiribati, Table 1 (continued)

Type	Element	Notes
Traditional and modern architecture and buildings	**Living vernacular architecture – rural setting**	The majority of buildings on Kiribati, both rural and urban, are "*kia kia*" houses with thatched roofs and open sides, built from local material, the roofs from pandanus leaf thatch (Fig. 7). Of both traditional and nontraditional (wooden or concrete walled) houses, the majority still have a thatched roof. On the outer islands, almost all "habitable" buildings are built in the "traditional" style, and almost all cinder block buildings are quickly abandoned. Unfortunately, many village dwellings on the outer islands lie abandoned and dilapidated because of the mass exodus to South Tarawa; however, people retain their ancestral "outer islands" land as potential areas of refuge to which one can return from the capital. The move "back" to the outer islands is specifically supported by the policies of the new government.
	City village – vernacular architecture of "urban" capital on South Tarawa	With regard to architecture, the only urban center in Kiribati, South Tarawa, remains mostly traditional and vernacular with rural character and structure of the households and their surroundings. The high population density caused by constant in-migration pressures from outer islands is achieved by the large household sizes and close proximity of the huts to each other (Royle 1999). The growing population of the capital island is largely accommodated in moderately traditional vernacular styles, but often using "new" materials – mostly due to depletion of traditional resources (Royle 1999). The "rural" character (a majority of the population still participating in traditional primary production) of the capital is mostly connected with poverty and affordability of "modern" materials.
	Ceremonial buildings – *mwaneabas*	*Mwaneaba* is a community meeting house for villagers or any recognized group of people where social or ceremonial occasions are held and public affairs discussed (Geddes 1982). The public *mwaneaba* are of similar design to the residential huts, but on a larger scale and built to a set form: they have a steeply pitched roof which comes quite close to the ground and is supported on pillars. The sides are open to allow the passage of air. The flaring-out of the roof line at the gable is the most characteristic feature of *I-Kiribati* architecture and can be observed in both thatched pandanus leaves and aluminum-roofed *mwanaebas*. The roofs of these structures descend very low to provide protection from rain and increase floor area as well as, more significantly, to provide maximum shade (Royle 1999).

climate change and other environmental pressures are taking their toll not only on the population but also on heritage preservation strategies. Human adaptations to the environments (although *not without environmental consequences* in themselves) can be seen all over Kiribati, in the ubiquity of "transported landscapes (see Table 1)." Throughout Remote Oceania, initial emphasis was

Archaeology and Cultural Heritage in Kiribati, Fig. 4 Cultural Landscapes of Gilbert Islands. Top left: Giant swamp taro pit on Abaiang; Bottom left: crossing on an outrigger from South to North Tarawa; Right: Fish trap on the ocean side of Abaiang. (Photos: AM Kotarba-Morley)

upon fragile but highly accessible resources of high food value (protein – especially shellfish), sometimes to the virtual exclusion of agriculture, and agricultural activity elsewhere was probably subordinate to foraging in most early colonizing phases (for the case of Yap see Fitzpatrick 2008). It is, however, important to stress that some resources were more resilient than others, for example, shellfish compared to flightless birds. We propose here that the cultural heritage of

Archaeology and Cultural Heritage in Kiribati, Fig. 7 Abandoned vernacular household on Abaiang. (Photo: AM Kotarba-Morley)

Kiribati should include maritime and coastal cultural landscapes, aquaculture, vernacular architecture, agroforestry (i.e., transported landscape), and other forms of traditional knowledge (e.g., Fig. 8) with oral history and folklore tackled separately.

Compared to other island groups in the Pacific, including the atolls of the Marshall Islands, Kiribati is in urgent need of systematic survey, site mapping, and systematic archaeological excavation to better document the sequence of island settlements, the impact on resources, and cultural transformation over time. Radiocarbon dates are few and far between, and in some cases, inadequately described, including problems associated with dating charcoal of plant species that have not been properly identified. At a regional scale, the position of the Gilbert Islands Group at the crossroads of Micronesia and Polynesia could provide the opportunities for finding additional evidence for long-distance migrations and trade extending to more distant islands and archipelagos, to complement the atolls' rich oral tradition of population movements. The discovery of pre-European

contact human burials might also yield aDNA to better understand genetic affiliations with other Pacific populations, although aDNA and other important biomarkers are not readily preserved in tropical environments (Morley 2017).

Cultural Heritage Protection and Tourism

Many cultural monuments and historical buildings are in disrepair, both on South Tarawa and on the outer islands. Ad hoc conservation is inadequate and continuous management practices and plans for the future with allocated resources need to be developed. This is also extremely important in light of the growing (although still very small-scale) tourist industry.

As part of UN Small Island Developing States (SIDS), a group of countries spread across the Atlantic, Pacific, and Indian Oceans, as well as the Caribbean and South China Seas and recognized as among the most vulnerable states in the world, Kiribati is working with the United Nation's Sustainable Development Goals. Plenary Panel on The Role of Culture in the Sustainable Development of SIDS held in Mauritius emphasized the issues of: (i) cultural identity and diversity; (ii) protection of tangible and intangible heritage; (iii) incorporation of local languages and traditional knowledge in formal education; and (iv) the economic opportunities provided by culture, in particular through cultural industries. It also "expressed strong and enthusiastic support for the recognition of culture as an indispensable and all-pervading component of human living and development. Mention was also made of 'Culture' as a fourth pillar of sustainable development" (Ikhlef 2014). Upholding these values and agendas, the consultation draft of the Kiribati 20-year Vision 2016–2036 (KV20 2016) states that "the nexus between tourism and culture is one of the priority areas for the KV20. It is in this context, that Government will strive to safeguard, revive and promote tangible and intangible cultural and historical heritages evident across the chants, music, dance and craft heritage sectors as well as the significant remnants from World War II" (KV20 2016: 44).

On a national scale, the local museum and Cultural Centre (Te Umwanibong) has a regional mission catering mostly to local primary and secondary schools, documenting the oral traditions of the outer islands and forming a great foundation for future development. Currently, considerable effort is being expended promoting heritage to outsiders; however, this has been taken over by, in lieu of government funded initiatives, tourism agencies such as *Tobaraoi*.

Future Directions

In terms of future directions, we argue that international conservation standards need to be adapted to suit regional purposes using scientific knowledge, for example, concerning climate change-driven shore erosion and sea-level rise. We strongly believe that the development of management plans and strategies should be undertaken on-the-ground, in cooperation with relevant stakeholders, and by local institutions, rather than by fly-in fly-out consultants. This is crucial, and while extremely challenging to achieve, the top-down approach in designing, championing, and implementing cultural and heritage sensitive agendas, policies and education curricula is the first step in which the foundations for capacity building and future bottom-up initiatives might best be achieved.

Archaeologists, historians, documentalists, archivists, and cultural heritage professionals

often find it difficult to "compete" for funding, permissions, and attention of governmental employees, diplomats, and dignitaries with "real life solutions" projects such as those preventing diabetes, dealing with water resources management or sustainable fisheries. Although it is much easier to sell the benefits of such projects to the general public, culture should be treated as one of the key pillars of sustainable development and should be imbedded in the core of educational curricula to expand public awareness of its importance. By becoming increasingly sensitive to heritage issues, engineering companies and NGOs could work in unison with researchers to achieve better opportunities for archaeological and heritage data acquisition and sharing, especially in such a vulnerable environment that might disappear within our lifetime.

There is a startling lack of comprehensive heritage legislation across many countries in Remote Oceania, especially those that do not follow American models, with issues of land ownership (land belongs to the clan and not to the country) making it difficult to "formulate or implement appropriate legislation for this purpose" (Thomas and Teaero 2010). In 2017, Kiribati adopted "An Act to regulate shipping, to update and modernise law relating to shipping to give effect to certain international maritime conventions and for related purposes" called in short "Maritime Act," 2017. Although word heritage is not mentioned in the document, the act has powers that could be used to protect Underwater Cultural Heritage including that of Wreck and Salvage Ordinance 1966 that is a similar regime to that in the UK, such as Receiver of Wrecks, Salvage, and Receiver of Wreck fees.

Additionally, the Environmental Act of 1999 has objectives "to protect, conserve and promote heritage" and Heritage is defined as including "a place, feature, structure or object that has aesthetic, archaeological, historic, cultural, natural, scientific or social significance or other special value for the present community and for future generations." Section 20 on the Contents of environmental impact statement prescribes that proposed and existing developments shall: (t) include a site survey report concerning National Heritage items or traditional artifacts as specified by the Minister acting in accordance with the advice of the Cabinet (Environment Act 1999, §20). Inclusion of heritage protection (including that of cultural heritage) under Environmental Act seems to follow the Australian federal model of "Environment Protection and Biodiversity Conservation Act of 1999," which also automatically provides for World Heritage Properties. In a similar vein, the Environment Act 1999 provides for regulation of the Phoenix Island Protected Area, which is the only WH site in the country.

Attempts have been made to incorporate specific issues of land ownership in the Pacific into legislation (e.g., Spennemann 1992; Thomas and Teaero 2010) but some archaeologists advocate that it should be through education rather than legislation that cultural heritage management practices are changed (Williamson 2001; Thomas and Teaero 2010). It is widely recognized that capacity building and training are key, but this can only be successful if interest is raised at an early stage of education. Job security, status, and pay are important considerations for young graduates so training and funding should be directed at selected individuals who are to be provided a pathway towards respectable and secure jobs and who would use the knowledge to promote further cultural education in the future.

Archaeology and Geography

David Chicoine
Department of Geography and Anthropology, Louisiana State University, Baton Rouge, LA, USA

Introduction

Scientific field archaeology has always relied on the methods, tools, and techniques of geography, geology, and other earth sciences. In the specific case of geography, with its core interest in the study of natural and human features across space, its contributions to archaeology have been multiple, transformative, and enduring. This is not surprising in light of the empirical nature of most archaeological inquiries and the need to record the location of remains. Although geography and archaeology are close parents and enjoy a mutually beneficial synergy, archaeologists have historically benefited more from geography – especially from major technical developments in mapping sciences, paleoclimatology, and geomorphology – than the other way around.

At the most basic level, archaeological surveys and excavations are anchored in mapping and surveying techniques. At a broader conceptual level, both archaeology and geography are concerned with the relationships between humans and their environments and their analysis through time and space. Indeed, beyond field methods, site formation processes, and spatial analyses, archaeology and geography share common research interests including the origins of agriculture, human-environmental relations, and the ways through which humans perceive, organize, modify, and engage with places including buildings, public symbols, and landscapes.

This essay offers an overview of the technical, methodological, and theoretical engagements between archaeology and geography. Building upon a review of the epistemological foundations of both disciplines, as well as their historical contours and interactions, four main areas are explored: (1) the applications of geospatial methods; (2) the contributions of Quaternary science, paleogeography, and paleoclimatology; (3) the intellectual cross-pollination between human geography, integrated geography, and the study of human-environmental interactions through time and space; and (4) the input of the geography of space and place in the development of landscape archaeology, phenomenology, and the study of ancient anthropogenic settings.

Definition

From its etymology couched in the "description of the earth," geography's traditional objects of study are varied and include things, peoples, and natural features. Indeed, as pointed out by William Hughes (1818–1876), geography is more than learning the names of places. Geographers study the distribution of humans, processes, and phenomena across the surface and subsurface of the planet. Because space and place affect a variety of topics, geography has the potential to be interdisciplinary. While early approaches emphasized the mapping and spatial distribution of natural and human phenomena, chronology and the study of time have gradually gained more weight, and longitudinal and historical perspectives have complemented synchronic ones. For instance, and with respect to the physical features of the earth and their changes through time, field archaeologists have gained significantly from advances in geomorphology and the recording and understanding of site formation processes.

Geography is a vast discipline that studies both natural and cultural phenomena. Hence, it has historically been polarized into two broad fields interested in the processes and patterns of natural environments (i.e., atmosphere, hydrosphere, biosphere, geosphere) at one end and in humans and their interactions with different types of variables (e.g., environmental, economic spatial, natural, social, political, religious) at the other. Several different iterations of geography integrate physical and human geography in various shapes and forms (e.g., environmental geography).

Historically, the tools and methods of geography have clustered into four major foci including spatial analyses, area studies, human-environmental relations, and geosciences. In relation to archaeology, most input, transfusion, and cross-pollination can be found at the level of survey and mapping techniques (including recent innovations in remote sensing); geospatial analyses (including recent advances in computer-aided mapping); human-environmental interactions (including human-plant interactions, human-animal interactions, and landscapes); the study of space, place, and settlements (including Walter Christaller [1893–1969] Central Place Theory); and Quaternary science, especially paleoclimate reconstructions (including the seminal work of Wladimir Köppen [1846–1940]).

Historical Background

By the eighteenth century, geography as a discrete discipline was part of most academic curricula in Europe. An early holistic view of geography was formulated by Alexander von Humboldt (1769–1859) in his *Cosmos: A Sketch of a Physical Description of the Universe* originally published in German in 1845 (Humboldt et al. 1849). A few decades later, Thomas Henry Huxley (1825–1895) – in his *Physiography: An Introduction to the Study of Nature* published in 1877 – presented a new form of geography and emphasized the empirical collecting of data over sole theoretical debates.

Exploration in the eighteenth and nineteenth century was a significant stimulus to both archaeology and geography as field disciplines. Fieldwork by Humboldt, Thomas Jefferson (1773–1826), John Lloyd Stephens (1805–1852), Frederick Catherwood (1799–1854), Ephraim George Squier (1821–1888), Ernst W. Middendorf (1830–1908), Clarence Bloomfield Moore (1852–1936), and Max Uhle (1856–1944) offered pioneering models. Napoléon Bonaparte's expedition to Egypt (1798–1801) had laid prior foundations for empirical and material collecting for both disciplines.

Epistemologically, geography and archaeology share many central tenets, most traceable to the Enlightenment and the birth of modern geosciences. The work of paramount figures in geology, paleontology, biostratigraphy, and prehistory such as Nicola Steno (1638–1685), James Hutton (1726–1797), George Cuvier (1769–1832), Carl Ritter (1779–1859), Charles Lyell (1797–1875), and Arnold Henry Guyot (1807–1884) was formative. In sum, the past is different from the present and is knowable through empirical observations. Natural processes are uniform, and their study can inform on similar processes in the past and their role in geological transformations (i.e., concept of uniformitarianism). Material remains survive, accumulate, and can be recovered. Younger geological strata typically sit atop older deposits (i.e., law of superposition), and their stratigraphic study can shed light on sequences of occupation, chronologies, and biological and cultural transformations. Advances in geosciences impacted archaeological methods, in particular excavations techniques as exemplified in the pioneering stratigraphic recording of Jacques de Boucher de Perthes (1788–1868), Eugène Dubois (1858–1940), Tessa Wheeler (1893–1936), and Mortimer Wheeler (1890–1992). The principles of geology, stratigraphy, and superposition also influenced the classification efforts of early antiquarians, collectors, and prehistorians including Christian Thomsen (1788–1865), Jens Jacob Asmussen Worsaae (1821–1885), and Gabriel de Mortillet (1821–1998).

Archaeology and geography, in particular biogeography, cultural ecology, and environmentally inclined studies, also owe to developments in naturalism, evolutionary theory, biology, adaptation, and social evolution and the key works of Humboldt, Charles Darwin (1809–1882), Huxley, Herbert Spencer (1820–1903), Alfred Russell Wallace (1823–1913), and Edward Burnett Tylor (1832–1917). The publication of Huxley's *Physiography* in 1877 was particular influential. From that standpoint, evolutionary archaeologists and geographers recognize that the concept of adaptation can be applied, albeit in different ways, to both cultural and biological studies. Cultural adaptations can be material, linguistic, behavioral, and so on, and the concept of social evolution

must not be conflated with the culturally constructed idea of "progress," as well as teleological and unilinear evolutionary models (e.g., Lewis Henry Morgan [1818–1881] *Ancient Society* published in 1877).

Although archaeology and geography share many epistemological, methodological, and theoretical tenets, very limited formal interactions and explicit conceptual discussions are documented before the second half of the twentieth century. Some overlap can be found in the writings of Friedrich Ratzel (1844–1904), Ellen Churchill Semple (1863–1932), Ellsworth Huntington (1876–1947), and Griffith Taylor (1880–1963) and the development of the concept of anthropogeography and subsequent models of so-called environmental determinism. Nevertheless, the historical contours of both disciplines align well.

The rejection and criticism of unilinear evolutionary ideas and models of the nineteenth century paved the way to the development of the concept of culture area and subsequently culture core. The idea that human cultures could be delimited in space based on linguistic, material production, and other cultural traits was key to the formalization of the cultural historical methods. Franz Boas (1858–1942), Robert Lowie (1883–1957), and Ruth Benedict (1887–1948), among others, promoted the idea of geographically distinct culture areas or culture blocks recognizable by their shared combination of traits. Through that normative view, human cultures are bound together through common and distinct norms. In that "aquatic" view of culture, time and space flow like water (so-called "ripple effect"). Culture contacts are constant and a function of time and space. More similar assemblages will be closer in time and space than less similar assemblages. Hence, by mapping trait distribution, one could establish the boundaries of a culture and its historical particularities. In geography, this era of research was characterized by regional area research and the collecting of descriptive information on places. Key figures in regional geography include Paul Vidal de la Blache (1845–1918), Alfred Hettner (1859–1941), and Richard Hartshorne (1899–1992). In American archaeology, culture history is perhaps best represented in the work of Alfred V. Kidder (1885–1963), William Duncan Strong (1899–1962), James A. Ford (1911–1968), Irving Rouse (1913–2006), and Will Carleton McKern (1892–?) (i.e., Midwestern Taxonomic Method).

Professionally, the Royal Geographical Society was founded in England in 1830, while in the United States, the National Geographic Society was formed in 1888. Both have been active in supporting archaeological fieldwork and exploration. A few decades later, the American Association of Geographers (formerly the Association of American Geographers [AAG]) was organized in 1904 in Philadelphia, the hometown of AAG's founder William Morris Davis (1850–1934). This boom in geography was closely tied to colonial enterprises, the extraction of resources, and the need of colonial authorities and companies for maps. From that standpoint, the emergence of archaeology is somewhat analogous, yet perhaps more complicated and multifaceted. Indeed, archaeology emerged as a discipline through multiple and fragmented fields including prehistory (anchored in geology), antiquarianism (based in collecting and the emergence of nation-states), classical archaeology (linked to art, esthetics, and architecture), and ethnography and sociocultural anthropology (grounded in the study of indigenous peoples).

Following the revival of ecological concerns under the banner of neo-evolutionary movements, archaeologists regained interests in the environment. This was not without input from cultural anthropologists and geographers including Leslie A. White (1900–1975), Carl O. Sauer (1889–1975), and Julian H. Steward (1902–1972). As such, environmental functionalism and processualism integrated paleoclimatological tools to the reconstruction of ancient environments and their impact on human adaptations. The pioneering work of geologist Gerard de Geer (1858–1943) on dating ice retreat in Scandinavia using varve deposits and E. J. Lennart von Post (1884–1951) on pollen grains to study postglacial floral change paved the way for the more systematic consideration of paleoenvironmental studies. The later study of Mesolithic Star Carr by Grahame Clark (1907–1995) is exemplary of

the importance of studying paleoenvironments and human adaptations.

Interest in the influence of ecological conditions on settlement patterns was further investigated by Steward and associated with the development of the cultural ecological approach to settlement archaeology. While recognized as the first American anthropologist to adopt an explicit materialist approach and focus on ecological factors, Steward's work influenced several archaeologists studying the origins of agriculture including Robert Braidwood (1907–2003) in Iraq, Richard S. MacNeish (1918–2001) in highland Mexico and South America, Robert C. West and Pedro Armillas on the Mexican *chinampas* ("floating gardens"), Donald D. Brand (1905–1984) in Mesoamerica, Joseph R. Caldwell (1916–1973) on interaction spheres in Eastern United States, and Gordon R. Willey (1913–2002) in the Virú Valley in Peru.

Cultural ecological influences in archaeology also came through the work of Sauer, Karl W. Butzer (1934–2016), David R. Harris (1930–2013), William M. Denevan (1931–), Kent Mathewson (1946–), Billie Lee Turner II (1945–), and others. Of those key figures in environmental and historical geography, the work of Sauer – in particular his *Agricultural Origins and Dispersals* published in 1952 – has been of significant impact in archaeology and paleoethnobotany. Influences can be seen in the work of Deborah Pearsall (1950–), Dolores Piperno (1949–), James A. Zeidler (1949–), and others.

Methodologically, the first application of remote sensing in mapping and imaging goes back to 1891, when a camera was attached to a blimp. Yet, scientists had to wait for the commercialization and militarization of airplanes for aerial imagery to become systematically relied upon. This was pioneered by Charles Lindbergh (1902–1974) and Anne Lindbergh (1906–2001) in Central America in 1929. A new era of remote sensing imaging was launched. Two years later, Robert Shippee (1910–1989) and George R. Johnson (1900–?) were leading an aerial photography expedition to Peru, and a decade later, Paul Kosok (1896–1959) and Richard Schaedel (1920–2005) were using aerial photographs to investigate the Nasca lines, irrigation systems, and ancient settlements in coastal Peru.

The quantitative revolution in geography coincided with the rise of processualism in archaeology and interests in systems theory, statistics, and the myriad applications of computers. This laid the bases for later innovations in Geographic Information Systems (GIS). Well-known geographers of this era include Fred K. Schaefer (1904–1953), Waldo Tobler (1930–), William Garrison (1924–2015), Peter Haggett (1933–), Richard J. Chorley (1927–2002), William Bunge (1928–2003), Edward Augustus Ackerman (1911–1973), and Torsten Hägerstrand (1916–2004).

The quantitative revolution and developments in spatial analyses, computing, and remote sensing contributed in major ways to the transformation of field archaeology. These innovations can be grouped under the banner of geomatics and include tools and techniques used in land surveying, remote sensing, cartography, GIS, global positioning satellite systems (GPS), photogrammetry, geophysics, geography, and other forms of earth mapping.

Critical geography, which arose as a critique of positivism in an analogous manner to post-processual and contextual archaeology, contributed significantly to bringing to the forefront existentialism and phenomenology to the archaeological study of ancient monuments and landscapes. The work of Yi-Fu Tuan (1930–) is perhaps most influential in geography and archaeology as seen in countless landscape studies.

In sum, the intellectual history of archaeology and geography shares many parallels, from their nineteenth-century reliance on evolutionary theory as applied to social formations to shifts toward area studies and culture history from the 1920s and the turn to positivism, spatial analysis, and processual approaches in archaeology in the 1960s. By the early 1980s, both archaeology and geography were undergoing reactions to the strictures of positivism, leading to pluralistic and more humanistic theoretical approaches.

Key Issues/Current Debates

Beyond regional geographies, archaeologists have borrowed and continue to be influenced by developments in geography, including tools, techniques, methods, and theories. While most geographical applications have been at the low-range, field-level archaeological research, higher range engagements with human-environmental relations and the concepts of space and place can also be recognized.

Geospatial Methods

Geomatics, also known as geospatial technology, is the utilization of computers in cartography and topography. Rapid progress in geospatial technologies is linked to advances in computer hardware, computer science, and software engineering, as well as airborne and satellite remote sensing. Geomatics methods are varied and include digital theodolites, distance meter total stations, spatial analysis, GIS, Geographic Information Science (GIScience), remote sensing, and GPS.

Remote sensing in archaeology allows to collect data beyond traditional excavations and survey methods. As such, any techniques used to acquire information through indirect means can be considered remote sensing. Data are obtained about the earth from measurements made at a distance and can come from many sources including satellite imagery, aerial photography, and handheld sensors (e.g., magnetometers, electrical sensitivity detectors, GPS units, ground-penetrating radar [GPR]). Results are obtained by contrasting archaeological features with the natural background. These contrasts are referred to as anomalies.

The development of remote sensing owes to rapid advances in technology, as well as the changing needs in the discipline. Demographic explosions on the planet have contributed to the increased need for cost-effective methods to locate, map, and acquire information from sites before they disappear. Considering that pedestrian surveys are becoming increasingly expensive, remote sensing allows to investigate large regions at low costs.

Broadly, methods in remote sensing archaeology can be aerial or terrestrial and rely on photogrammetry, radar technologies, light detection, geophysics, and more. Aerial methods include photography, multispectral, hyperspectral sensors, thermal infrared multispectral scanners, color infrared film, microwave radar, and satellite imaging (e.g., LiDAR [Light Detection and Ranging], SAR [Synthetic Aperture Radar]).

LiDAR measures the distance to a target by illuminating that target with a pulsed laser light and measuring the reflected pulses with a sensor. Laser return times and wavelengths are used to make digital 3D representations of the target. LiDAR can be airborne or terrestrial. Its applications in archaeology range from planning field operations to mapping features beneath forest canopy and providing data on features otherwise invisible from the ground. LiDAR also allows for the creation of high-resolution digital elevations models (DEMs) that can reveal micro-topography otherwise hidden by vegetation. LiDAR-derived products can be integrated into GIS.

The field of satellite archaeology has proven useful in detecting potential archaeological features as well as monitoring the state of preservation and destruction of visible ones. High-resolution satellites with thermal and infrared capabilities can be used to identify and locate sites of potential archaeological interest. Such technology typically works for features around one or two meters in depth and is based on the processing of images with the objective of defining anomalies at the surface of the earth. Landscape features such as soil, vegetation, geology, and human-made structures can be identified. Noninvasive methods are also significant to monitor sites that face encroachment from human and natural activities. Recent work by Daniel A. Contreras, Neil Brodie (1954–), and others on site inventories and evaluations of looting and destruction based on satellite images is particularly significant.

With respect to site inventory and reconnaissance, remote sensing archaeology has been particularly productive in regions covered with thick vegetation including the Petén region of northern

Guatemala. Remote sensing is also useful to gather data on deforestation and anthropogenic landscape alteration. Canals and irrigation systems have been successfully delineated and mapped using SAR, a type of radar that is sensitive to linear and geometric features on the ground.

Terrestrial or ground-based geophysical methods employ instruments on or near the surface of the earth including magnetometry, electrical resistivity, electromagnetic conductivity, GPR, and terrestrial LiDAR. Magnetometry is usually the most productive technique and provides fast results over broad areas on the formation of magnetic anomalies including firing the soil, the accumulation of fired artifacts, variations in soils and sediments, surface soil layers magnetically enhanced, the removal of magnetically enriched topsoil (e.g., ditch), and the accumulation of topsoil (e.g., mound), imported stone, and iron-bearing artifacts. Electrical resistivity measures soil resistivity to electrical current and depends on material type, moisture, dissolved ion content, density, and pore space. Electromagnetic conductivity is based on the inverse principle and the fact that a highly resistant material is a poor conductor (e.g., floors, walls). GPR sends rapid pulses of microwave energy which pulses can reflect on buried features (e.g., walls, floors, pits, rubble).

Recently, remote sensing techniques have been complemented by 3D scanning which has multiple applications in archaeology and the recording, study, and reproduction of objects. The purpose of 3D scanning is to create a point cloud of geometric samples on the surface of an object. Overall, two types of 3D scanning technology exist: (1) contact and (2) noncontact (active or passive). Contact 3D scanners probe the subject through physical touch (e.g., coordinate measuring machine), while noncontact methods utilize different types of emissions including light, ultrasound, or x-ray. LiDAR scanners, handheld laser scanners, structured-light 3D scanners, and volumetric techniques (e.g., computed tomography, magnetic resonance) all have archaeological applications.

The quantitative revolution in geography and the development of GIS have impacted in significant and enduring ways field archaeology and the analysis of spatial data. Indeed, much if not all the information collected in archaeology is wholly or partially spatial. Following its introduction in archaeology in the mid-1980s, its tools, techniques, and softwares became standard by the mid-1990s. GIS can be defined as computer systems which main purpose is to store, manipulate, analyze, and present information about geographic space. GIS is not a single computer software; rather it is a spatial toolbox with various softwares. It is often compared to AutoCAD, because both allow one to draw a map, but GIS is different and more powerful since it can be manipulated by its database and provides predictive power. Four main subsystems can be identified including data entry, spatial database, manipulation and analysis, and visualization and reporting. The central component of any GIS is its database. It must store locational component (i.e., position in geographic space), topological component (i.e., logical relationships between objects), and attribute component (i.e., characteristics).

GIS has various and useful applications in archaeology. Elevation modeling, or the representations of surface of terrain, is useful since it can produce derivatives valuable to understand human occupation (e.g., slope, ridge-drainage index). Related analytic methods include visualization of topography, cost-distance and least-cost pathway analyses, the analysis of visibility and intervisibility, simulations of natural processes (e.g., flooding, erosion), virtual reality and visual reconstruction, spatial interpolation (i.e., the use of spatial characteristics of a variable and the observed values of that variable to guess the values of that variable at unobserved locations), and predictive modeling. The latter, although widespread in archaeology, is also the most controversial. Its main goal is to generate spatial models that have predictive implications for future observations. Geospatial technologies as well as geophysical methods are a central part of the growing field of landscape archaeology.

Quaternary Science, Geomorphology, and Paleoclimatology

In the realm of physical geography, archaeologists have interfaced most with the disciplines of biogeography, oceanography, paleoclimatology, landscape ecology, geomorphology, pedology, hydrology, hydrography, paleogeography, and Quaternary science. Paleoclimatology encompasses a broad array of studies and datasets that can be of great use to archaeologists in reconstructing paleoenvironmental conditions and their role in the development of human societies. Paleoclimatologists typically rely on proxy evidence, especially for periods predating the twentieth century.

Popular proxies in reconstructing past climatic conditions include dendrochronology, sclerochronology, palynology (pollen), and glaciology. Since annual tree rings depend on water, solar energy, and temperatures, dendrochronology, or the study of tree rings, can bring insights into patterns of precipitation and droughts. Sclerochronology, or the study of growth rings in calcium carbonate skeletal material (e.g., mollusk shells, fish otoliths, corals) and in particular their geochemical composition (stable isotope analysis, elemental ratios), can help reconstruct ancient sea surface temperature and other oceanic conditions. For instance, the ratios of different types of oxygen isotopes in water are dependent on temperature and salinity and are incorporated into the calcium carbonate. This field of study is part of the broader discipline of paleoceanography. While this is true in corals, shells, and otoliths, in glacial ice cores, paleoclimatologists usually reconstruct air temperature, rather than sea surface conditions. Glaciologists study the various inclusions found within ice cores including gas like CO_2, ash, pollen, and dust, with the objective of reconstructing ancient climatic conditions, especially air temperatures and things such as land use change, pollution, and precipitation.

The study of pollen, or palynology, can shed light on the presence of plant species and help in estimating ancient natural ranges of certain ecosystems and biotopes as well as artificial changes in land use. Changes in the relative frequencies of different types of pollen can provide longitudinal perspectives on changing patterns of vegetation cover.

Geosciences, in particular geomorphology, have been influential in the study of site formation processes in archaeology. Michael B. Schiffer's *Behavioral Archaeology* published in 1976 exposed the basic difference between natural (N-transforms) and cultural processes (C-transforms), which has since then been refined and integrated into more complex models.

Human-Environmental Relations

In reaction to the static, classificatory approach to environmental variables, a branch of archaeology promotes a more active perspective on geography. Such a contextual approach favors the integration of zooarchaeology, paleoethnobotany, geoarchaeology, and cultural ecology into archaeological studies. The movement was also a reaction to environmental determinism and favored historical particularist approaches to understand the interactions between humans and their environments. The work of Sauer and his disciples – as part of the Berkeley School of Latin American Geography – was particularly influential and helped shape more contextual and environmental iterations of archaeological research.

Debates in geography, cultural ecology, and historical particularism were seminal in the adoption of cultural ecological – and later political ecological – frameworks in anthropological and environmental archaeology. Steward, with the publication of *Theory of Culture Change: The Methodology of Multilinear Evolution* in 1955, was instrumental in the popularization of cultural ecology approaches and their instrumentalization in archaeology, in particular settlement pattern studies. In order to reconstruct the ways in which the environment influences human adaptations, one needs to consider its particular historical trajectories and developments through time.

In geography, Butzer developed the concept of contextual archaeology in *Archaeology as Human Ecology: Method and Theory for a Contextual Approach* published in 1982. He advocates for the study of archaeological sites as part of broader ecosystems and their various environmental

subsystems. While this is reminiscent of Lewis R. Binford's (1931–2011) technomic, sociotechnic, and ideotechnic subsystems, Butzer contextual and human ecological approach to archaeology recognizes five main themes including space, scale, complexity, interaction, and stability. These concepts, while geographical and biological, have significant potential in archaeology. It is different from anthropological archaeology and suggests to move human ecosystems and geography from the background to the foreground in a more dynamic perspective.

Cultural ecology was also central to studies of the origins of agriculture and their ecological and economic roots, especially as seen in the work of Alexander Chayanov (1888–1937) and Ester Boserup (1910–1999). The latter's publication in 1965 of *The Conditions of Agricultural Growth* was significant and impacted archaeological research, including the work of Billie Lee Turner II on ancient agricultural systems and environmental transformations of Maya groups in the Yucatán. In South America, the publication of *Cultivated Landscapes of Native Amazonia and the Andes* by William Denevan in 2001 represents an important contribution from the field of human geography and archaeology. Recent research by John H. Walker, Manuel Arroyo-Kalin, Daniel A. Contreras, José Iriarte, David Beresford-Jones, Volker Sossna, and others on South American historical and prehistoric ecologies, paleoenvironments, and anthropogenic landscapes continues this tradition.

Space, Place, and Landscape

A major contribution of geography to archaeological studies has been to shift the fundamental units of analysis from the "site" or "settlement" to broader spatial categories including the region, area, and landscape. At the same time, scholars have realized the importance of considering the natural features of the landscape in the formation of world views and cultural realities. Landscape history and archaeology investigate the engagement of people in the past with their environments, including the ways those are constructed, modified, and perceived. This field of study emerged through interdisciplinary interactions between historical geography, archaeology, architecture, and phenomenology. *The Morphology of Landscape* published by Sauer in 1925 and *The Making of the English Landscape* by William George Hoskins (1908–1992) in 1956 were key in developing the concept of cultural landscapes.

Landscape archaeologists place emphasis on the relationships between material culture, anthropogenic modifications, and nature. Although some landscapes can be considered natural and devoid of human modifications, landscape archaeologists focus on cultural landscapes, those spaces modified by humans, sometimes over long period of time. Modifications can be small or large, from garden patches to monumental earthworks and agrarian infrastructures. Places and spaces – as well as natural features – are seen as dynamic agents that helped shape human actions through time.

The archaeological study of space and place owes to the work of geographer Yi-Fu Tuan, in particular his *Space and Place: The Perspective of Experience* published in 1977. From the standpoint of architecture, the work of Amos Rapoport (1929–), especially his *House Form and Culture* published in 1969, is fundamental and contributed to the establishment of environment-behavior studies. The contributions of Edward T. Hall (1914–2009) on proxemics and Erving Goffman (1922–1982) on performance and symbolic interaction have also helped shape archaeological approaches to human-space interactions. Concepts from environment-behavior studies have been widely applied in the anthropology, ethnohistory, history, and archaeology of the built environment, especially in urban, ceremonial, and monumental settings as seen in the work of Jerry D. Moore, Stephen H. Lekson, Michael E. Smith, Setha M. Low, and Denise Lawrence.

Concepts from phenomenology and the writings of Maurice Merleau-Ponty (1908–1961), Edmund Husserl (1859–1938), and Martin Heidegger (1889–1976) also contributed a great deal to advances in the archaeology of landscapes and monuments, as exemplified in the prolific literature on architecture, material culture, interpretive

archaeology, and the phenomenology of landscape. The writings of Ian Hodder (1948–), Julian Thomas (1959–), Michael Shanks (1959–), Michael Parker Pearson (1957–), and Christopher Tilley feature prominently as examples of the archaeological study of past experiences and perceptions. Other landscape archaeologists include Sam Turner, Tony James Wilkinson (1948–2014), Bruno David, Adam T. Smith, Stephen J. Lansing, Clark L. Erickson, Nicole Branton, Steven A. Wernke, James A. Delle, and Barbara Voss. Landscape archaeology has explored cultural identities, political hegemonies, religious movements, and their manifestations in space, among other things.

More recently, archaeologists have further drawn from developments in the social theorization of space and place as materialized in the increased importance of the concept of social memory, persistent place, and sacred geographies. The archaeology of memory has been particularly productive as exemplified in the work of Ruth M. Van Dyke and Susan E. Alcock, among others.

Future Directions

Future directions in the cross-fertilization of archaeology and geography are multiple and have the potential to open exciting and innovative avenues for research. While most contributions have typically flowed from geography into archaeology, historical and environmental geographers are increasingly cognizant of the value of longitudinal and archaeological perspectives.

One can expect that continued advances in remote sensing, computer-aided mapping, and other geospatial technologies will lead to new and fruitful applications in archaeology. As such, the now systematic training of archaeologists in GIS is a testimony to its enduring status. The implementation and greater accessibility of drones should also help aerial photogrammetry becoming a staple in field archaeology. At the same time, the widespread and public accessibility of satellite imagery raises issues and concerns regarding the protection of archaeological sites. With respect to the conservation, promotion, and appreciation of cultural heritage, advances in imaging technologies, 3D scanning, and virtual realities are paving the way to new forms of museological experiences and appreciation of ancient cultural, spatial, geographic, and material realities. Beyond terrestrial applications, geography and archaeology also have a future in space archaeology, or the study of human-made objects and traces found in space.

The training of archaeologists and geographers is increasingly done hand in and hand. In North America, this is done under the banner of geography and anthropology departments (e.g., Louisiana State University, Colorado State University), while in the United Kingdom, several undergraduate and graduate programs in geography and archaeology exist in geosciences and earth sciences departments (e.g., University of Cork, University of Edinburgh, University of Southampton). A more sustained and ubiquitous combining and integrating of geography and archaeology in both undergraduate and graduate curricula would contribute to their synergy and applications to the study of the past and present human phenomena.

Archaeology and Politics

Rafael Pedro Curtoni
CONICET, Faculty of Social Sciences, UNICEN, Olavarría, Buenos Aires, Argentina

Introduction

This entry considers the institutionalization of the archaeological discipline in the context of modern Western science and puts forward the idea of "archaeology as politics." The analysis takes place from a South American perspective and takes a different stance from the widespread treatment on the subject which is based on the presumption of a division between science and politics as exclusive domains (although recognizing some influence of the latter). That is, it is not the intention of this entry to differentiate between archaeology and politics as separate spheres, which would imply the acceptance of the possibility of being able to "manage" at will the political side of archaeological practice in time and space. On the contrary, it is considered that archaeology is politics and its disciplinary practice inscribes power-knowledge relations both at the micro- and macro-political levels.

The dual anchorage of archaeology in modernity and in the unfinished transmodern reconfigurations predefines the political origin of absolutely all actions and choices involved with

the production process, reproduction, and management of scientific knowledge. This is related to the geopolitical conditions implicated in the generation of knowledge and which preestablishes the preeminence of science over other forms of knowing. Geopolitical contexts refer not only to the physical space but also to the sociopolitical, historical, epistemological, academic, and editorial (among others) scenarios, through which certain forms of knowledge are generated and installed over others (Walsh 2007). To account for this, some historical trends will be discussed that have occurred in South America in general and in Argentina in particular, regarding the interrelationships between archaeological practices, theoretical frameworks, and political contexts. The geopolitics of knowledge impact not only the forms and conditions of producing and reproducing knowledge (i.e., science, academia, publishing companies) but also the definition and management of places of interest (e.g., historic sites, protected areas) and materiality (e.g., memorials, monuments, heritage, artifacts, museums) promoted by different sectors and actors with commemorative, recreational, educational, and cultural purposes. In this context, archaeology as discipline provides discourses, narratives, lifestyles, places, and objects located in time and space, thereby becoming a contemporary device in the classification of stories, landscapes, people, and their relationships from an Anglo-Saxon, colonial, and modern knowledge perspective.

Historical Background

Archaeology from a Political Perspective

Anthropology and archaeology as disciplines have a modern origin and are associated with the centers of political and economic power of liberal industrial countries (e.g., England, France, Germany, and the United States). Since its beginnings in the mid-nineteenth century, social sciences in general and archaeology in particular developed in relation to these power centers and became institutionalized as a knowledge-producing enterprise. In this historical constitution of disciplines in Western thought, there are two foundational assumptions that characterize modern social sciences (Lander 2003). On one hand, the existence of a universal metanarrative from which all peoples and world experiences are classified and ranked, with European industrial society considered the most advanced expression of this development. In this context, the first "articulations of cultural differences in chronological hierarchies" appear, activating classifications of premodern, traditional, and/or primitive. From this perspective the forms of knowledge that were developed to understand the "other" societies came to be the only valid, objective, and universal ways of understanding the world. Through this Eurocentric view which organizes time and space, a mechanism of colonial and imperial knowledge was installed and naturalized that preestablished the superiority of the product of science over other forms of knowing (Restrepo 2007). The ideal of knowledge in modernity, besides being characterized by its objectivity and universality, is predefined as disembodied and ahistorical, that is, by its possibilities of transcending and disregarding persons, times, and places. This is connected with the ontological rupture between body and mind, an initial separation in the modern Western tradition, which places human beings in an external position and instrumental to their environment (Lander 2003). This reinforces abstraction and distancing as main heuristic elements in the construction of knowledge.

According to the Porto Rican philosopher Maldonado-Torres, if scientific knowledge is recognized as the only valid way of knowledge, cognitive faculties in racialized subjects (the "other" colonized) are denied, which provides the basis for the ontological denial and epistemic disqualification of the latter (Maldonado-Torres 2007). Descartes' cogito ergo sum gives primordial importance to the epistemological and expresses the sense of coloniality of knowledge, "others do not think, thus they are not." So, "not thinking becomes a not being signal in modernity" (Maldonado-Torres 2007: 145), and thereby exclusion, subalternation, and/or denial mechanisms are generated for all that is different from the way of thinking of the modern, Western, and

white "us." The epistemic disqualification referred to by Maldonado-Torres can be linked to the concept of "epistemicide" proposed by Santos (2006), to refer to the death of alternative knowledge caused by the installation of the idea of scientific knowledge as the only valid and rigorous way of understanding the world. Consequently, this monoculture of knowledge, as it discredits and disqualifies "others," shrinks and reduces the present by eliminating different contemporary conceptions that do not fit within modern canons and scientific principles (Santos 2006).

Moreover, there is no doubt that the relationship between politics and archaeological practice has begun with the emergence and development of the discipline in the nineteenth century (Trigger 1989). However, discussions about the political implications of archaeology or on the uses and abuses of the past emerged only in the last decades of the twentieth century. Archaeologists' late treatment of these discussions can be seen as a result of disciplinary institutionalization which sought to cover archaeology with scientific status guaranteeing objectivity and neutrality. Simultaneously, the development of the firm belief that archaeology is synonymous with the past helps to install the view of the professional's role as being free from the vicissitudes and particularities of its own time. In that sense, the practice of archaeology, under the precepts of modern scientific thought, is inscribed and mediated by the denial of its contemporaneity reflected mostly in political, Eurocentric, and racist terms. Some academic theories, such as diffusionism and evolutionism, were the conceptual frameworks for the construction of national identities in different countries of South America and which white Europeans used to legitimate their treatment of indigenous peoples. At the same time, different archaeological investigations sought to demonstrate the historical discontinuities between high pre-Hispanic cultures and contemporary native groups. The cultural historical synthesis of large regions and areas was one of the main objectives of the South American archaeology in the early decades of the twentieth century. In this context, diffusionism and racial studies were one of the main mechanisms to explain the migration patterns of human groups through space and time (Politis 1995).

It was not until the 1970s and 1980s that scientists began to reflect deeply on the close relationship between the archaeological work and nationalist practices, as well as the sociopolitical contexts in general. The emergence of Latin-American social archaeology in Mexico and Peru, with its theoretical orientations in historical materialism and neopositivism, saw attempts to explain social phenomena scientifically. This movement sought to link the past to the present and aimed to be a weapon of liberation for the people. Issues relating to their origin and status as exploited or the transience of social classes, institutions, and behavioral patterns were explored (Lumbreras 1974). Latin-American social archaeology was therefore characterized by the development of an original theoretical approach which sought to provide the basis for generating emancipatory political positions rather than academic positions. The most significant contributions were made in Mexico, Peru, Venezuela, Dominican Republic, and Cuba; however, the influences of this approach were restricted to those countries during the 1970s and early 1980s. In this regard, it has been suggested that social archaeology was associated with temporal contexts where the political model of the nation state tended towards a Marxist ideology (Oyuela-Caycedo et al. 1997).

Moreover, not all Marxist archaeologists ascribed to the tenets of the Latin-American social archaeology. Among them, some American archaeologists close to Marxism began to explore the political implications of the discipline and archaeological praxis and to discuss issues relating to the procedures and uses of the past such as ownership of archaeological materials, authenticity, ethnicity, restitution, and cultural resource management (Trigger 1989; Kohl and Fawcett 1995; McGuire et al. 2005). The emergence of post-processual archaeology in the Anglo-Saxon context also contributed to a deeper analysis of the relationship between archaeology and politics and broadened the discussion about the implications of professional practice and the role of the archaeologist (Shanks and Tilley 1987). The organization of the first World Archaeological Congress

(WAC) in 1986 promoted the analysis and discussion of politics in archaeology and especially its inclusion in the research agenda (Ucko 1987). The founding objectives of the WAC, which among other things sought to promote indigenous peoples and defend their rights, were to activate relationships with and the participation of archaeologists from peripheral countries and engage in their sociopolitical issues. These were novel proposals that challenged the idea of a neutral archaeology and promoted other ways of considering professional practice.

In the 1990s, the vision that archaeology had consolidated, due to its origin, an inescapable political dimension and that nationalism is just one of many possible manifestations of this nature can be expressed both in its political and scientific activities (Silberman 1995). Some observations may be made in relation to this idea of archaeology and also in reference to the excision of political and scientific domains. Regarding the former, this assumption is still accepted without much discussion, and it appears that the political domain in archaeology is *one* dimension (Kohl and Fawcett 1995). This idea implies that the discipline must inevitably have other dimensions that are not political and that there is some possibility of disaggregating its components. Moreover, considering scientific and political activities as independent areas, besides representing the possibilities of disaggregation of archaeological dimensions, is part of the neoliberal agenda which is sustained by ideas of neutrality, detachment, and objectivism. As mentioned at the beginning of this entry, by its origin, scope, implications, overt and hidden actions, and omissions, archaeological practice is always inherently political. In this decade, and in some South American countries, constitutional reforms have recognized the preexistence of indigenous peoples and have consecrated certain fundamental rights such as the communal ownership of land as well as rights to health care, to education, and to practice their culture. These rights, established by the nation state, will become in the future significantly relevant for the indigenous peoples in their relationship with archaeologists.

The beginning of the twenty-first century heralded the deepening and multiplicity of voices associated with the politics of knowledge in archaeology. This development gave rise to changes in the ways archaeologists began to consider archaeological practice through an understanding of the plurality of agents involved. In recent years there have been, in different contexts of world archaeology, diverse theoretical and methodological approaches in the light of decolonizing thought that have tried to account for the involvement, participation, and coproduction in archaeological research projects of actors and historically marginalized sectors (McNiven and Russell 2005; Smith and Wobst 2005; Gnecco and Ayala 2010).

In its disciplinary history, much of South American archaeology has developed behind closed doors privileging knowledge construction from a Western and white perspective. One could argue that this way of looking at archaeological practice in much of South America is a result of the theoretical and methodological influences from the historical cultural school and the processual archaeology that predominated and still influences this part of the Americas. Moreover, in Argentina in particular as well as in some other South American countries, democratic governments have alternated with coups d'état and military governments that have significantly influenced the development of archaeology in these regions through the promotion of national archaeologies (Politis 1995). In general and in brief, it can be said that in Argentina during democratic times, science advanced and academic activity progressed in many directions. During these moments, archaeological research consolidated, systematic financing research projects began, important national and international scientific events occurred, and new undergraduate and graduate careers were created. Conversely, during military periods, there were setbacks in research, some universities and anthropology careers were closed, and there was ideological persecution and discrimination (Politis and Curtoni 2011).

In recent years, especially since 2003, the Argentine government of President Néstor Kirchner promoted a progressive national and popular

model, with a clearly defined foreign policy and South American connection, which meant a change in style and conception of international integration of the country. In the twenty-first century, this has been favored by the surging conditions in the South American scenario, generally characterized by a neoliberal exhaustion – through policies of market liberation; the emergence of social and political movements that put forward alternatives of production and management; the revaluation of the State versus the market, shown in the regulation and promotion of social equality; debt reduction and the proposal of autonomous relations with the United States; and, finally, the search and strengthening of processes of regional integration represented by the Mercosur and Unasur (Ayerbe 2011). This economic, political, social, and cultural repositioning, which has occurred in several countries in South America, has affected and still are affecting, to varying degrees and depth depending on national contexts, the ways to consider archaeological practice as well as its own theoretical elaboration. In Argentina, in recent years, discussions about the ethical dimensions of archaeological work and heritage management have been activated, and the participation and involvement of indigenous peoples in archaeological research projects has seen the emergence of new issues and problems of inquiry. For example, issues relating to local situations have been considered and claims and disputes raised by local groups (e.g., indigenous peoples, peasants) have been addressed in archaeological congresses (e.g., relating to territorial dispossessions, the destruction of sacred places, repatriation of human remains and associated materiales, and the destruction of sites).

Key Issues

Archaeology, Knowledge, Politics, Power

Since its conception, production, reproduction, distribution, and consumption, knowledges generated within academic institutional frameworks bear their geopolitical, geo-historical, and geocultural imprints ("knowledge" is used in plural in this entry with the intention of presenting the idea that knowledge in singular refers to the Eurocentric view while the plural makes reference to the Latin-American conception of the possibility of multiple knowledges). Referred to as the body politics of knowledge (Castro Gomez and Grosfoguel 2007), knowledges possess a place, context, body, color, and gender in their origin (Castro Gomez and Grosfoguel 2007). Thus, they are contingent, situated, and traversed by relations of space and power. These conditions may also express the senses of coloniality of power, knowledge, and being, which characterized ways of knowing developed and imposed in colonial modernity (Lander 2003). The concept of the coloniality of power refers to strategies of modern exploitation and domination that had their origins in the naturalization of racial hierarchies and the ordering and classification of "otherness." The coloniality of knowledge is related to the central role of epistemology in the process of elaborating knowledge, which can allow reproducing colonial schemes of thinking and controlling all forms of subjectivity, of culture, and of production and reproduction of knowledges (Quijano 2003). Finally, the coloniality of being refers to the colonized subjects' lived experiences and histories and their impact on language forms (Maldonado-Torres 2007). Under these conditions, Western science's epistemic colonialism is imposed from the definition of the "zero" point as the main model of knowledge through which the world can be observed from a neutral, objective, and absolute locus (Castro Gomez and Grosfoguel 2007).

In Argentina, the thinker Arturo Jauretche reflected on the reality of the country in the 1950s in terms similar to those involved in the concept of the coloniality of power, by considering the geopolitical and chronopolitical dimensions of knowledge. In his essay on "pedagogical colonization," he said that under the appearance of universal values, "only relative values corresponding to a certain time or geographical location, whose appearance of universality arises solely from the power of universal expansion given by the centers that originate them" are still being introduced (Jauretche [1957] 2004: 99). Also, through national projects,

the intellectual elites or "intelligentsia," according to Jauretche ([1957] 2004), identified the universal values of "culture" enshrined by the centers of power, thereby excluding all preexisting understandings. The ideal promoted by the "intelligentsia" was to create Europe in America through the destruction of indigenous peoples who were seen to be an obstacle and through the denial of all local values and possibilities of regional creations. Thus, the process of "Europeanization that was practiced did not consist in the incorporation of European values to the existing culture, but in its outright derogation" (Jauretche [1957] 2004: 102).

Hegemonic narratives are furthermore added that imposed some axiomatic formulations, discursively constructed, posing the lack of continuity between the pre-Hispanic past and contemporary indigenous peoples. In his book, *The Prophets of Hate and Yapa* (*Yapa* is Quechua word meaning gift that the seller gives to the buyer), Jauretche ([1957] 2004: 102) expressed, "The misunderstanding of our pre-existing as a cultural, or rather, understand it as anti-cultural, contributed to the fact that the pre-existing were deprived of all means of expression. It was not enough with the massive replacement of the native population by immigration flow. Intelligence became 'intelligentsia' and assuming that culture was exclusively imported it became one of the most effective tools to uproot the local elements of pre-existing culture." The idea of progress in America could materialize if both the past and the present were denied, "hence the insistence of American denial and anxiety about being European. This historical pattern caused a method that later became norm. Reality was replaced by abstraction" (Jauretche [1968] 2002: 30).

The effects of the coloniality of power and relationships with knowledge management have been criticized and denounced by various Argentine thinkers such as Ortiz Pereira, Manuel Ugarte, Scalabrini Ortiz, Jauretche, and Fermín Chávez, who sought to think of reality both from their own and from concrete needs. It was a way of seeing things "from here" because "the inability to see the world from ourselves has been systematically cultivated in our country" (Jauretche [1957] 2004: 108). Pre-Hispanic past denial and the denial of contemporary indigenous peoples became part of the essence of the modern cosmovision and modus operandi established from colonial order. For example, in the search for defining the identity of the pampas promoted by state authorities and based in the multicultural synthesis, "the indigenous" fluctuates in a complex way, being at times present as a figure of recognition and reparation and at other times absent ignoring their current claims and concessions. This is a consequence of the action of two simultaneous processes called the "specific invisibility" and "generic visibility" (Curtoni and Chaparro 2008). Specific invisibility refers to the strategies of concealing, silencing, and denying that operate on the "indigenous being," on the concrete needs of the communities, their rights, and claims, as well as on political activism and its representatives. Different narratives have been attempting both to enunciate the absence of indigenous people in the region and to challenge the legitimacy of existing identities. In parallel, generic visibility mechanisms are generated, generally staged by state power, and associated with reparation, recovery, and revaluation of "the indigenous" actions. The preferred forms of expression of this process are the materialization or the monumentalization of "something" referred to as the indigenous world, without any discussion and consensus with local communities about what and how and with the intention of visibilizing actions and demonstrating political awareness. These constructions objectify indigenous agency and relationships. The official authorities' discourses are also activated which promote multicultural integration as a way of overcoming historical controversies (such as indigenous and white Creoles). In this search for Pampa identity, the "indigenous" fluctuates unanchored in different forms, being at times synonymous with the past, in the best case, in miscegenation, and in others and expressed as patrimonialized and/or monumentalized figures (Curtoni and Chaparro 2008).

These strategies, together with racist and ethnocentric elaborations, formed the basis of nation-constitution projects in different countries of South America in general and Argentina in

particular (Politis and Curtoni 2011). Social science and archaeological practice taking place in these spaces of power were not free of ideological-political influences promoted by the colonial modern imaginary. Thus, the criticism of the colonial construction of knowledges requires an epistemological-political positioning that attempts to "decolonize" disciplinary foundations. This dual dimension is expressed in terms of methodology with the statement that there are no definitive and unique rules which guide research (see Haber 2011), together with the acceptance of other views and extra-academic elements in the construction of knowledges and at the political level with the critique of science's hegemonic, globalizing, and exclusive stance. The premise of the decolonization of knowledge is to make clear the place and relationships from which knowledges are produced and to analyze the institutions that produce and/or are managers of it and point out its power effects. It also entails transcending the senses involved in the "zero point" challenging detachment and neutrality and recognizing contamination and agreement in the generation of knowledge (Castro Gomez and Grosfoguel 2007).

Future Directions

In this sense, what is necessary is not just alternative knowledge, but new ways of producing and reproducing them (Santos 2006). These could rise from an intertopic criticism about the global imposition of knowledge, leading to the promotion of different and multiple places of enunciation though interrelated, coproduced, and pluriversal. The practice of archaeology "from here" (Jauretche's) results in a rupture with the academic-scientific privilege and status as the legitimate producer of universal knowledge construction, and on the other hand, it activates decolonizing procedures of instituted knowledge (pedagogical decolonization), thereby promoting new ways of knowing. What is sought with these statements is that the construction of knowledge is historically situated, i.e., not Eurocentric or based on the scientific rationalism of liberal modernity. Overcoming Eurocentrism implies, among other things, an anchorage of space in terms of the spatial, social, bodily, linguistic, epistemic, and political sense so as to activate our incorporation in concrete spheres of pluriversality where other bodies, languages, concepts, other knowledges, and epistemologies coexist. These "other spaces," where different knowledges are organized together with other epistemologies, cosmovisions, and rationalities, are prior to the interests and motivations of the academic field. Therefore, neither do peoples and groups forming these spaces and knowledges, as well as the places themselves, need to be empowered (paternalist attitude quite common in some postcolonial and postmodern discourses) nor do they need the academic concourse or the "expert" wink to manage a position of credibility, legitimacy, and existence. On the contrary, it is essential to establish decolonizing processes at the subject's level in terms of its "pedagogical colonization," its scientific language and disciplinary practices, and its disincorporation, in order to overcome academic arrogance and the exclusion caused by epistemic hierarchies of the global coloniality and its incorporation – in the sense of embodiment – to local situations.

Throughout history and even in some current contexts, archaeology has developed and been installed as a hegemonic biopolitical device whose narratives construct and control stories, places, subjects, and their relations from a Anglo-Western, scientific, modern, and colonial production standpoint. Thus, archaeological practice is always inherently political, and it reflects in different ways and intensities the complex and dynamic interrelationships between interest groups, archaeologists, and sociopolitical contexts. The analysis of the relationship between archaeology and policy exhibits complicity between modernity and coloniality and the generation of knowledge as an ideological/political product. The subversion of this mode of production, which has been institutionalized and naturalized, involves at least the effort to place the constructions of knowledges together with and from local pluriversality and from geo-chrono-political

stances so as to invert the relationship and thus retrace the itineraries of the archaeological politics in the light of other interests and other ways of knowledge production.

Archaeology and the Emergence of Fields: Environmental

Keryn Walshe
Department of Archaeology, South Australian Museum, Adelaide, SA, Australia

Introduction

Environmental archaeology is both an extension of general archaeological principles and an area of study in its own right. Formally acknowledged in the 1950s, it has grown significantly since then – so much so as to give rise to the fear of ever-increasing "silos" in the discipline of archaeology. Environmental archaeology uses proxies to investigate site context and forensically pursues artifacts and ecofacts to elicit data. Rigorous taphonomic investigations are intrinsic to methods used in environmental archaeology.

Definition

Environmental archaeology investigates the site environment at the time of human activity. The principal aim is to determine the link between changing patterns of human activity and local, regional, or even global environmental change. In this way, the environmental record can be used to make causal inferences about changes in the archaeological record.

Humans continually respond to their environment and any change to their familiar surroundings invokes changes in their response. This change is discovered in the archaeological evidence through the use of a number of subdisciplines. For example, paleoethnobotany (study of fossil plant remains), zooarchaeology (the study of vertebrate remains), geomorphology (study of landscape formation), palynology (study of past pollen regimes), geophysics (study of dynamic landscapes), landscape archaeology (the cultural landscape of the site), human biology (human remains), and human ecology (living in the landscape) are some of the subdisciplines in environmental archaeology. Each subdiscipline offers a particular analytical methodology to investigate the past environment and its record over time. Change is scalar and can be anywhere from micro to macro. Smaller changes are generally harder to recognize in the archaeological record. Through the use of subdisciplines, a greater level of sensitivity can be applied, thus increasing the chance of successfully recognizing local, small-scale change. Identifying change on any level enables inter- and intrasite comparison and comparative archaeological analysis is the core of most archaeological research.

Historical Background

Environmental archaeology has been recognized as a serious component of archaeological investigation since the 1950s. The appointment of Frederich Zeuner as Professor of Environmental Archaeology at the Institute of Archaeology in London in 1952 allowed formal recognition of environmental archaeology as a substantial and significant subdiscipline of archaeology. Initially, the place of the natural sciences in archaeology was almost exclusively through the application of stratigraphy. Stratigraphy emerged through the efforts of geology to provide time lines for fossil finds and in so doing allowed a means of chronology to be applied to human occupation. Stratigraphy was also able to identify catastrophic environmental events such as sudden onset of aridity, floods, or lava flows. Such singular and dramatic, large-scale environmental events were readily recognized and their subsequent impact on

humans could be investigated as an individual focus in archaeological investigations. Matching stratigraphic change to a chronological phase has allowed changes in human response to be recognized and environmental interpretations to emerge. However, the nineteenth century saw archaeological endeavor subsumed to some extent by evolutionary theory and it was not until the early twentieth century that a broadening of the discipline really came about.

A key turning point in the approach to archaeology had already begun with Eric Higgs paleoeconomics and an equivalent impact was delivered by Graham Clarke through his work at Starr Carr. Starr Carr is a Mesolithic site located in Yorkshire, England, and is arguably one of the most significant sites studied in the mid-twentieth century. This site is considered to have truly set environmental archaeology on its path by providing a momentous leap from simply looking at stone tools in isolation to applying other lines of scientific investigation. Indeed, Clarke was able to inter-relate human behavior and their artifacts with the environment. In this way, changes in the artifacts became signatures of changes in human behavior over time. From here on, archaeologists were able to seek the causal effects of changing environments on human behavior over time. It also allowed the reverse to be investigated – human environmental impact causing landscape, ecological, and even meteorological change over time.

Key Issues/Current Debates

Two schools of thought have arisen in environmental archaeology which can be simplified into a regional versus single site approach (Evans 2003). Some archaeologists concentrate on single sites while others adopt a regional approach by investigating a series of sites usually linked chronologically and/or culturally. A region is generally geologically defined such as a valley or mountain range. It is possible to consider sites as a single entity within a broader cultural landscape and both schools of thought offer advantages and disadvantages. Regional approaches allow greater scope for identifying large-scale environmental change and its impact on a region. Regional approaches also enable intersite comparison and broaden the investigation by including, for example, exchange and transport routes. However, the disadvantage can be the lack of intense investigation at any one site, as offered in the single site approach. Perhaps a combination of both is ideal if not always practical.

The rise of environmental archaeology has also been expressed differently on different continents. O'Connor (1998) identifies a key difference existing in the 1980s between the United States of America and Britain. According to O'Connor, Britain was primarily focused on the "organic" content of a site while North Americans were primarily geologically focused. This could be an inevitable outcome considering the marked differences between these two continents in not only dimension, but also in geology, culture, and chronology.

Environmental archaeology does allow a site investigation to be reduced into many fields of enquiry. This fact has caused some concern, as expressed initially by Thomas (1990) and then considered by others (Wilkinson and Stevens 2003) in that environmental archaeologists operate outside of the mainstream of archaeology. Fear lies in the sublimation, or worse elimination, of archaeological aims and methods in the pursuit of identifying environmental change. The fact that environmental archaeology is independent of routine archaeological methods has been viewed as problematic and even threatening. For this reason, it is reliant on the archaeologist to synthesize the many streams of enquiry into a coherent interpretation that acknowledges the discipline for which it is written.

Others feel that the term "environmental archaeology" is redundant and all scientific pursuits relevant to archaeology are either bioarchaeological (zoology and biology) or geoarchaeological (sedimentology and pedology). This allows the archaeologist to maintain a clearer approach; however, if both are selected, then the whole reverts back to environmental archaeology! In the end, archaeology must remain focused on human response to localized change.

Environmental archaeology is investigated via key areas of exploration – geology (earth systems), zoology (animal systems), sedimentology (layering of soils and rocks), biology (ecosystems), botany (plants and floral systems), pedology (origin and change of soils), and taphonomy (site formation processes). These subdivisions fall into one of two key areas of investigation: via the organic or the physical. Bioarchaeology covers the former and geoarchaeology covers the latter.

Archaeological artifacts are composed of raw materials. These raw materials are termed proxies and it these proxies that are available for specific analysis. Proxies are more sensitive as environmental indicators compared to their "whole body" counterparts. A modern Australian kangaroo, for example, is a poor environmental indicator as its geographic distribution is continent wide and it has been on the same continent for many thousands of years. By comparison, pollen is a more sensitive indicator of the local environment. Preferred proxies are those with narrower geographic distributions or habitats and are themselves very sensitive to localized environmental change.

Proxies exist on macro- or microscales. Bioarchaeological macroproxies are mostly floral and faunal remains such as seeds, shells, bones, teeth, and insect carapaces and casings. Geoarchaeological macroproxies include sediments, soils, and rocks. Microscopic bioarchaeological remains include pollen, phytoliths (silica skeletons), diatoms (single celled algae), ostracods (bivalve crustaceans), and foraminifera (singled celled shelled animal). Microscopic geoarchaeology proxies include the chemical elements that make up soil and rocks. Most proxies are "ecofacts" as unlike artifacts, they are not directly attributable to human endeavor such as a wooden or stone implement. Ecofacts are not fashioned or manufactured for human purpose but provide an important opportunity for investigating the paleoenvironment. For example, meal discards such as shells found in Aboriginal middens are ecofacts. Midden shell is used extensively in archaeology to identify environmental change (through spectrum analysis, for example) and cultural change (through radiometric analysis).

Some proxies can be even further reduced into smaller elements and characterized to extract a finer level of information. However, all environmental archaeology effort is constrained and challenged by the degree of preservation operating across a site or region and the method employed. Sampling for microproxies relies on a high degree of structural preservation. Taphonomy investigates site formation processes and offers a means of determining and assessing degrees of site and artifact or ecofact disturbance and preservation. In using proxies, it is critical to be able to identify when a proxy is an unreliable agent due to significant bioturbation or other impact on the site.

Charles (1998), for example, investigated the use of dung-derived plant material in archaeological sites in Northern Iraq. In areas where animal dung is used as a fuel source, dung cakes offer a means of identifying local plants by identifying seeds passed out in the dung. As Charles (1998) points out, critical taphonomic issues are that the plants can be a mix of grazed, crop residue or wild plant fodder sources. Dung is also likely to be sourced from a range of animals and the variable impact of digestion on seeds needs to be understood. A further key point is that dung cakes are burned and only those that partially or completely survive this process are useful for analysis. Some of the dung cakes also contained dung pellets, offering a means of identifying which animals produced the dung. Dung pellets may also contain seeds or pollen. Charles (1998) was able to consider the taphonomic aspects effecting plant remains in dung cakes and then compare the interpretative data from the dung cakes and pellets with ethnographic information on animal husbandry and seasonal cycles of cereal cultivation. Importantly, these two interpretative frameworks were not in unison and Charles (1998) suggests that critical changes within husbandry at these sites can be linked to local environmental change.

By way of another example, Church et al. (2005) have provided results from the first archaeological investigation of Norse settlement on the Faroe Islands. This archaeological investigation makes use of the results of prior

paleoenvironmental investigations to assess the impact of early human economic practices. The archaeology explored reliance on and timing of animal husbandry, cereal production, integration of wild species, and sourcing different fuel supplies. Church et al. (2005) utilized animal and plant remains as vital proxies, integrated against the multiproxy approach employed previously in the paleoenvironmental investigations. By examining the animal bones in the excavations, it was recognized that Norse settlers commenced with a heavy reliance on puffins as a vital food source and the collection of driftwood, peat, and turf as fuel sources. This reliance on both food and fuel that was gathered from the natural environment altered the understanding of the beginnings of human settlement in this region. The eventual shift to the production of crops, husbandry, and managed fuel sources was matched against the environmental data to provide the contextual framework of Norse settlement on the Faroe Islands.

With multiple lines of investigation, the archaeologist is more likely to find at least one proxy from primary (humans bringing in materials), secondary (by-products of the processing), or tertiary (dumped rubbish) agents. Locating proxies also requires the application of purposeful sampling methods and it is here that the environmental archaeologist may seek the expertise of non-archaeological specialists.

Spectral analysis is a field of investigation used across the physical sciences. It offers significant potential for archaeology by identifying the elemental composition of proxies, a process known as "characterization." Characterization allocates the raw material of a proxy a unique signature or "fingerprint." The characterization of raw geological materials such as sedimentary rock (e.g., dolomite, basalt, and flint), sand or hematite or goetite rich clay pigments (e.g., ocher) is a key focus for geochemical investigation. Rock or clay from a quarry will have a different signature or "fingerprint" to rock or clay from another quarry. This uniqueness enables the distribution of objects to be mapped away from their quarry source. In turn, distribution routes of the raw material can be spatially located, thus connecting humans across different cultural and geographic landscapes. Characterizing ocher to its own quarry source is proving both successful and challenging as ocher is found to differ geochemically within as well as between sources (Popelka-Filcoff et al. 2008). Exchanged objects have also benefited such as ground edge axes manufactured from dolomite rock in southeastern Australia. Dolomite was sourced from very few quarries and traded out from those centers. By characterizing the dolomite, exchange routes across southeastern Australia have been established (McBryde 1984).

Trade and exchange routes originally identified through more traditional archaeological methods are now able to be refined by use of highly sensitive analytical instruments that rely on infrared spectroscopy. Finds, such as the 100,000 years old ocher grinding tools from Blombos Cave in South Africa, provide a range of samples capable of providing detailed environmental data. These tools include abalone shell, ocher, bone, and stone which are all significant for geochemical investigation.

Environmental archaeology commenced with an awareness of the value of data gathered directly from the site context. Looking back, the gathering of environmental data was comparatively coarse, relying largely on macroproxies and rarely on microproxies. The introduction of highly sensitive instruments offering a range of spectrum analysis has shifted the balance to microproxies. It has also, as a result of that shift, placed increasing emphasis on ecofacts whereby artifacts and ecofacts can hold similar weight in interpreting the site. Environmental archaeology has fine-tuned its approach in response to the increasing availability of highly sensitive analytical instruments as a valuable methodological tool.

Other preferred proxies are those that are keyed to a single level of water quality – fresh or saline. Proxies that can withstand brackish environments are poorer indicators than those that are associated only with either fresh or saline hydrological regimes. Declining levels of fresh water are often identified in archaeological landscapes as the primary cause of a shift in technology, economy, and even geographic with groups moving elsewhere. In this case, diatoms, foraminifera, or ostracods are sought out in aquatic sediments,

particularly lakes. These proxies are highly sensitive indicators of fresh or saline regimes and have proved successful in detecting varying water quality over long time scales (e.g., Gell et al. 2005).

The investigation of dune-fields is another key focus area for environmental archaeology. The occurrence and abeyance of dune-fields has long preoccupied human groups. Dune-fields are a natural feature but can be mobilized by deforestation. A major trigger for deforestation has resulted globally from humans seeking fuel and also fodder for domestic animals. Numerous settlements over time have been swallowed up by mobile dune-fields and the timing and consequences of this on human activity can be investigated through the characterization and aging of dune-fields (Hesp 2001).

Environmental archaeology through its reliance on proxies also requires a range or reliable datasets and reference materials. Diagnosis of animal and plant remains relies entirely on a comparative reference set. As found by numerous archaeologists, establishing such sets can be extremely problematic as it is also necessary to include as much demographic or seasonal variation as possible. Ideally each animal will be represented by male and female examples of juveniles, subadults, and adults. Such a plea was made by LeFebre (2007) during an investigation of the maritime economy on the coral reefs of the West Indies. Inevitably LeFebre was confronted with numerous fish bones and limited reference material. This is hardly an unusual situation and one that will continue to confront emerging environmental archaeologists. Fish are particularly sensitive environmental indicators. The need to identify to species level is critical if a robust environmental framework is to be established. Fish otoliths (earbones of fish) are an even more sensitive proxy than the fish itself, are species specific, and also offer data on the size and age of fish at death. Otoliths are structurally robust and preserve better than fragile fish bones, offering an almost perfect archaeological proxy. However, establishing adequate banks of otolith reference material requires high resource commitment and a skilled researcher to match archaeologically derived otoliths.

International Perspectives

The pursuit of environmental archaeology in Australia has progressed similarly to other continents after having commenced in a recognizable format since the 1960s. Australian archaeologists at that time were particularly aware of Higg's paleoeconomic models and Clarke's paleoenvironmental approach at Starr Carr. Australian archaeology has also demonstrated a bold approach to integrating science into the discipline. In the 1930s, for example, Norman B. Tindale was collecting raw sediment samples, charcoal, and ocher in the belief that future technology could provide analytical tools for dating and deciphering the elements there in. Over the last 20 years, there has been considerable effort made to find an increasingly diverse array of proxies analyzed by increasingly more sensitive and sophisticated instruments. As a result, proxies become ever smaller and more diverse, offering multiple possibilities for highly sensitive signatures of environmental change. Australia's greatest challenge is the size of its land mass and the relatively few well-described sites and even fewer fully analyzed excavation assemblages. The ratio of open to deep deposit (rockshelter/cave) sites is also significantly in favor of open sites. Preservation of bioarchaeological proxies in particular is poor for open sites, leaving the vast majority of sites reliant on geoarchaeological proxies for determining environmental change. The limitations incurred under such conditions can be alleviated to some extent by a regional approach in the hope that at least some rockshelter/cave sites will be recorded along with the numerous open sites. However, this in turn can be problematic in view of the size of the continent and the scarcity of well-described sites. This can lead to valiant but statistically challenged attempts to identify regional and chronological trends drawn from a few sites spread over vast distances. Aboriginal occupation of Australia is well over 45,000 years and this only compounds the problem of too few well-described sites.

Although Australian archaeology has been unhesitating in its incorporation of scientific principles into the discipline, it too is hampered by

minimal comparative reference sets of proxies and datasets. A hiatus in the 1980s saw numerous small research projects devoted to establishing proxy collections, but the more recent trend away from such core research has created a significant gap in valid reference material. A similar history exists with taphonomic reference material due to the demise of actualistic studies. Understanding growth rates and species diversity is also an under researched area and yet it is vital to making interpretations from elements such as bone and shell. Australia's unique environment with its consequent unique range of environmental agents needs to establish its own comprehensive data set rather than assume that data derived from other continental contexts is comparable. Happily, however, it is precisely Australia's unique situation with such a long era of hunter-gatherer occupation followed by the current and very brief era of colonial and pastoral settlement that offers enormous potential for environmental archaeology. Australia's way of life leads us to automatically look to the natural landscape to explain patterns of human occupation. The contribution from contemporary Aboriginal people has also enabled an inspiring approach in interpreting the relationship between humans and their environment.

A key difference between the Australian continent and other land masses is its hydrology. It is the driest continent on earth but capable of dramatic, short-lived floods and has very slow rates of soil deposition. All of this has great bearing on the preservation of archaeological deposits and proxies which in turn makes environmental archaeology in Australia unique. It also points out the urgency in generating our own data sets from a range of comprehensive biological, geological, and hydrological studies.

Future Directions

O'Connor (1998) and others (e.g., Evans 2003; Wilkinson and Stevens 2003) have pointed out that environmental archaeology is capable of reducing itself into innumerable pockets of research (soil, coins, trees, phytoliths, etc.). Although there is the potential for a "silo" effect as it is often known, it is rare that any one site offers an overwhelming range of proxies suitable for intense analysis. Most sites offer only a few well-preserved proxies. In addition, it is reliant on the archaeological team to ensure that clearly stated archaeological aims are established and the driving and unifying force for the environmental investigations. The strength of environmental archaeology lies in offering a holistic view of the relationship between past ecosystems and changing human response. Data collection and building reference collections needs to be more robust, geographically wider, diverse in species and genus, and longitudinal. There has been a step away from experimental (simulation) archaeology, due to recognized inherent problems of replicating human and/or animal behavior in controlled conditions. Environmental archaeology is only as valid and robust as its datasets and reference material. Fine scale data, such as growth rates (e.g., Langlet et al. 2006) and species identification, is demanded globally. There is also an urgent need for complex and longitudinal taphonomic studies. The vagaries of site preservation have been long accepted but the understanding of factors affecting the preservation of a site and its objects is still poorly understood in most instances. If proxies are to be selected for specialist analysis, archaeology needs to ensure that they are relevant to the site and that they have structural integrity. To make environmental archaeology more rigorous, taphonomic investigations also need to offer more concise identifications of the numerous agents of change operating across a site and identify the implications of this for the use of proxies.

The opposing side of field work is the pressing issue of making archaeological collections sustainable. Archaeological collections are notorious in collecting institutions for their high-end need for space compared to other collections. Spectrum analysis is able to investigate the matrix of any element, thus urging archaeology to retain almost the entire site rather than just the objects and modest samples of excavation sediment. The need for space will escalate exponentially if

collecting institutions allow archaeology to retain bulk samples and increasing amounts of ecofacts. This renewed interest in existing collections is extremely beneficial for research outcomes and for securing existing collections into the future; however, it is hoped that this is not at the cost of housing new collections.

The final challenge for environmental archaeology (as it is for archaeology generally) is to publish results more often and more widely. Too often it is only the environmental results that make it into the public domain rather than a broader and comprehensive contribution to the discipline of archaeology. Field activities such as excavation and surface collection continue to far outweigh the more laborious and in-house task of producing professional reports and peer-reviewed papers. It is vital that archaeologists offer the latter as some recompense for disturbing, or even destroying, cultural heritage sites.

Introduction

In this entry two closely linked archaeological fields are discussed: classical archaeology and historical archaeology. We share Thomas Patterson's (2001) externalist approach to the history of science, considering the discipline not only through changes in ideas and concepts but also as a result of intellectual moves linked to social changes. This theoretical stand pays attention to social and cultural issues affecting scholarly production in general and particularly archaeology.

Historical Background

The relationship between classical and historical archaeology is not a given fact but a chosen way of understanding the archaeology of societies with written records and concerned with Western tradition. It is thus a theoretical stand, informed by a redefinition of the field from the 1990s (Funari et al. 1999). Classical archaeology arose very early, at the beginning of the nineteenth century, as part of the imperial project of Western powers, being military in character, a conservative and male endeavor (Funari 2002). It started as an ancillary to history and classics, mostly as art history illustrating classical references to peoples and places. In epistemological terms, classical archaeology was established as a philological discipline, concerned with cataloguing and typology, and dependent on the mastering of Greek and Latin. First and foremost, a classical archaeologist was a military male with a good command of classical languages and literature as well as an historian. Until last quarter of the twentieth century, the field continued a conservative course, but since then classical archaeology gained a lot of traction from social theory and theoretical discussion in general, even if continuing in line with traditions of the field, such as having a good command of classical languages (Shanks 1996).

Historical archaeology developed in a completely different historical and intellectual context. It started in the United States in the 1960s, as an anthropological field interested in the material culture of Anglo-Americans. Although it departed from a completely different place in comparison to classical archaeology, the American discipline was also reactionary, focusing on the study of the White Protestant Anglo-Saxons (WASP) and praising the founding fathers (Orser 2001).

In the following decade, as a result of substantial social and academic changes in the United States, in the wake of the civil rights, antiwar, and feminist movements, new issues were included in historical archaeology, such as the study of subordinate groups, African-Americans, the Irish, and women. Years later, new concerns from outside the USA led to the inclusion of global issues, and the discipline started to discuss all historical periods with written documents, much beyond the original fifteenth century onwards thrust as was prevalent in the USA (Funari et al. 1999). From the late 1990s, there have been a growing number of people putting together the archaeology of Greece and Rome (classical archaeology) and the archaeology of

other historical periods, including the historical archaeology of the modern period.

Key Issues/Current Debates

Historical Archaeology

Historical archaeology as the study of societies with written records comprises such diverse subjects as ancient Egypt, Greece, and Rome, medieval societies, and modern settlements but also sites in China and Vietnam, thus including all the continents. This broad perspective is now widely accepted, even if historical archaeology is still mostly a term used to refer to late medieval and modern material culture as attests a leading journal in the field, *International Journal of Historical Archaeology*.

Disciplinary boundaries are always a thorny issue (Burke 2006: 13–4), as it concerns not only an epistemological question (what is and what is not within the field) but an administrative one, related to power in academia and society at large, as stressed by Pierre Bourdieu (1988). Any study of the discipline is thus embedded in power relations and politics (Meskell 1998), and our own stand here is to contextualize the field and our own stand, as we are archaeologists from the periphery. We thus reject any essentialist standpoint, as if a specific definition should be correct, for we acknowledge the diversity of the field and different approaches. In this entry we will deal with two different traditions in the field: European and North American historical archaeology.

European and North American Traditions

The epistemological differences between European and North American traditions are rooted in the different historical and academic contexts. Archaeology started in Europe in the nineteenth century as a counterpoint to classical philology and history. Archaeology was the material study of ancient civilizations considered as the intellectual ancestors of the Western powers, Egypt, Greece, Rome, and later on Mesopotamia and Palestine. Different civilizations flourished in those areas in ancient times due to the mastering of writing, a key feature of civilized life. History itself was thus defined by writing, and due to an evolutionary approach, there was a perception that there was ever-growing progress from the most ancient civilizations to the apex of industrial capitalism (Nitecki and Nitecki 1992).

Archaeology was thus historical archaeology, in so far as it dealt with civilizations using writing to store knowledge. Prehistory and prehistoric archaeology developed later to study material remains from much earlier people who lived before writing was invented.

Until the 1930s at least, archaeologists working in Europe were using philological and historical tenets in archaeological interpretations, particularly in historical or protohistorical contexts, such as Flinders Petrie, Gustaf Kossinna, and Gordon Childe. However, the role of writing has been challenged from different quarters, from the early twentieth century. First and foremost, the influx of social theory revealed the relevance of other sources of knowledge and questioned the well-established pivotal role of writing (Burke 2006).

This move affected archaeology by emphasizing identity issues (Kristiansen 2009). Archaeology has moved to pay attention not only to distant civilizations but turned also to more direct national roots, turning to the Anglo-Saxon in Britain, to Germans in Germany, to Vikings in Scandinavia, or to the Celts and Iberians in Spain. It is thus possible to conclude that in the European tradition historical archaeology emerged from a number of epistemological and political issues: the pivotal role of writing and the role of a historical framework in interpretation. In this tradition, historical archaeology studies us, the civilized people, producers of learned culture as expressed in writing, and it is thus linked to nationalist and imperialist contemporary interests and concerns. The conflict of different nation states in Europe led also to interpretive conflicts, such as the different identification and interpretation of Celtic, Germanic, and Slavic remains. Historical archaeology in the European tradition has been rooted in modern identity issues and to national pride and prejudice.

Historical Archaeology in the American Tradition

In the United States, archaeology started in two different ways. First, as in Europe, it was established as the study of civilization. The American Archaeological Institute was set up in 1879, and soon afterwards America was digging in the Old World, as attests the American School at Athens (1880) and the American School in Rome (1895) and in Jerusalem (1899). Classical and oriental archaeology were thus in the same European style and it still is a most active tradition in the USA. It was and in a way still is concerned with studying the Western tradition, rooted in the both the Middle East through Judaism and Christianity and in the Greek and Roman classical heritage.

Prehistoric archaeology though was from the start concerned with the other (Hartog 1998), native inhabitants of the continent, taken as completely foreign to the civilized American cultural milieu. It was thus only too natural that archaeology in this vein was taken as part of the discipline concerned with the other, anthropology. While linguistics studied Indian languages, biological anthropology studied bodies, social anthropology studied living Indians, and archaeology was to explore dead Indians through their remains. The American Anthropological Association was established in 1902.

It is thus clear that the archaeological study of colonial and national sites in the USA developed only lately. It started as the archaeology of historical sites still very much concerned with some national iconic sites. It was only in the 1960s, thanks not least to the influx of Roman archaeology as practiced in Britain, that historical archaeology took root in the country, searching for the equivalent of Romans, that is, the first introducers of writing and civilization to the land: the early Anglo-Saxon settlers of America. The Society for Historical Archaeology was established in 1967 and in 1989 the AIA, the American Schools of Oriental Research, and the Society for Historical Archaeology held the first Joint Archaeological Congress, further strengthening the link of historical archaeology concerned with modern roots and the other archaeological institutions equally in search of American and Western civilizations.

Changes in European and American Historical Archaeology (1970s Onwards)

Since the 1970s, historical archaeology in the USA gained traction and increasingly broadened its scope, as attests the seminal publication of James Deetz (1977). The original focus on WASP material culture shifted gradually to include other groups, such as African-Americans (Orser 1988), and then a plethora of excluded subjects, including women, Chinese, and more. The publication of Eric Wolf's classic in 1982 signaled this trend towards the excluded and beyond the traditional emphasis on written evidence for interpreting material culture. Colonialism has thus also been put at the heart of the discipline (Hicks and Beaudry 2006; Kristiansen 2009).

Historical Archaeology and Capitalism

According to Hicks and Beaudry (2006), Charles E. Orser, and Mark Leone, among other pioneering Marxist historical archaeologists, such as Randall McGuire, managed to define historical archaeology as the study of capitalism and the resulting modernity and globalization. The Annapolis Project (1981) is a clear case of successful interpretation of material evidence as part of the capitalist order of things. The project was also responsible for the study of the subaltern, as with the case of the remains of African slaves, workers, and exploited people.

Orser (1996) produced a most convincing argument for historical archaeology as the study of capitalism, spreading from Europe and uniting the whole globe. Capitalism was not only the economic driving force, but it redefined the whole set of social relations (Leone 1999). Power relations, domination and resistance, and identity processes were among the subjects dealt with through the identification of historical archaeology and the study of capitalism. In recent decades, under the influx of other interpretive frameworks, most notably those criticizing normative schemes, several scholars have refined or even contradicted the overwhelming and

totalizing power of capitalism. Some stressed symbolic issues (Hodder 1995), class conflict (McGuire 2008), and the role of writing (Little 2007; Johnson 2010). However, it should be noted that some of those scholars were not American and this leads us to the role of peripheral outlooks.

Historical Archaeology in Latin America

Archaeology in Latin America started very early as it did in the United States, first as a search for Old World roots in the nineteenth century (Ferreira 2010) and then prehistoric archaeology developed for nationalist purposes in countries such as Mexico and Peru, but also in countries with less impressive prehistoric monuments. This was the case in Argentina with its quest for the earliest human remains worldwide. The study of Iberian settlements though developed late, as this was mostly as a result of the influence of the United States newly established field of historical archaeology. However, while the USA was always a democratic country with a wide variety of social movements, Latin America faced the contradictions of the Cold War (1947–1989), including dictatorships. Historical archaeology developed late and at first as an empirical endeavor, in tune with the times. The waning of authoritarian rule led to a freer and more diversified study of historical archaeology. The inclusion of the subaltern, such as maroons, slaves, and women, led to a growing social commitment of the discipline, culminating in the study of repression and the struggle for freedom (Funari 2001; Funari et al. 2009). Two different theoretical trends developed. Under the influence of the USA, historical archaeology has mostly been interpreted as the study of capitalism after the arrival of the Europeans in the Americas. Others though were keen to explore how the historical experience in Latin American has been also patriarchal, hierarchical, and prone to personal and patronage relations, as such the importation of the concept of historical archaeology as the study of capitalism was not always useful. On the contrary, the specificities of non-capitalist features in Latin America necessitated the study of material culture through different, local lenses (Funari et al. 1999). The diversity of approaches has fostered the interest of people outside to understand it, discussing such theoretical concepts as transculturation, patronage, and métissage among others.

Classical Archaeology

Classical archaeology was only recently affected by theoretical discussions in the discipline. At the conference celebrating the centenary of the Archaeological Institute of America, the leading classical archaeologist Colin Renfrew (1980) pondered the three the most relevant achievements of the institute: the extension of the field of American archaeology in other areas and seasons, including the "ancient world"; the promotion of academic criteria for the discipline through its publications; and the creation of a discussion forum in this institutional space.

Renfrew interpreted classical archaeology as part of the so-called great tradition of the Western canon: the reading of classical literature in the original and a philological approach to the world. We can add that this tradition was grounded on repetition, memorization, and description. The past was always better than the present, as in other traditional cultures stressing past models rather than aiming for innovation, such as is also the case with the traditional Chinese worldview. This led to classical archaeology being from the start mostly descriptive and lacking interest in theoretical issues. It was only through the push of Anglo-Saxon anthropological moves, first new archaeology in the 1960s and 1970s and then post-processual archaeology, from the 1980s, that it reacted in a creative way. Let us turn to the main traditions of classical archaeology.

Traditions of Classical Archaeology

Over the last few decades, classical archaeologists from various parts of the world reacted to the challenge, rethinking their epistemological frames. We will study four main perspectives here: the German, English, Italian, and French. We start with the German, for it is the earliest and in a way the most traditional and probably also the most impervious to social theory issues,

as the term is interpreted in the Anglo-Saxon world.

German Tradition

German classical archaeology predates the country and refers not to Germany but to German-speaking people. This is a key aspect of classics and classical archaeology in the German style: it is a culture area (*Kulturkreis*). Classics played a unique role in German-speaking areas such as Prussia but also elsewhere. It was a romantic way of fostering nationalism and identity in different contexts. The *Gymnasium* (grammar school) was the basket of the intelligentsia. Classical archaeology started as a search for material evidence relating to classical literature in the German-speaking principalities, municipalities, and even empires (such as the Austro-Hungarian), Greece and Italy, geographical concepts in search of a nationality. It is no coincidence that the 21st of April (date of the foundation of ancient Rome) 1829, a number of scholars, artists, and diplomats founded in Rome the *Istituto di Corrispondenza Archeologica*, aiming at studying monuments of ancient art, inscriptions, topography, and beyond. It was transferred to Berlin, in Prussia, in 1832, becoming imperial after the unification of Germany in 1874. Several branches were established and classical excavations spread throughout the Mediterranean.

German classical archaeology followed strict procedures in terms of publications paying attention first and foremost to complete catalogues with the largest possible cross-references. It was also subjected to nationalist and racist trends from society and academia, such as the search for superior Aryans and Indo-Germans: racist interpretations were widespread everywhere as attested to, for example, in books by Vere Gordon Childe, not to mention more imperialist archaeologists such as Mortimer Wheeler, both founders of the Institute of Archaeology, University College London. In recent decades, classical archaeology in German-speaking countries, even if still keeping most of the array of learned descriptions of sites and artifacts, is ever more open to social theory, German style, meaning the consideration of theories relating to religion, to economics, to iconography, and so on. This acceptance of a specialized theoretical discussion is thus usually concerned not with social theory in epistemological terms but with specific interpretive tools considered as useful for understanding specific sets of material culture.

The English Tradition

Classical archaeology started early in Britain, and as with classics in general, it was mostly influenced by German scholarship. It was, however, from the start less obsessed with cross-referencing *ad nauseam* and was open to social theory, as attested to by two of the leading icons of the discipline of archaeology, Gordon Childe and Roger Collinwood. From those early-twentieth-century days dates also the preoccupation with interpreting material culture per se, not as mere parts of a narrative established by ancient literature. This led to a late-twentieth-century emphasis on the interpretation of material culture outside the framework of classical literature (Snodgrass 1987) and expanded the interpretation of periods before the use of writing, such as the Iron Age in several parts of Europe. Later on, issues such as colonialism, imperialism, and nationalism were used to study different classical subjects, such as obscure periods of Greek history (Morris 2000), so much so that for Morris (2000: 3) "archaeology is cultural history or it is nothing." The entangled relationship between past and present and reception and interpretation has also been stressed by such classical archaeologists as Richard Hingley and David Mattingly, using medium range theory, German style, and epistemological discussions about the discipline.

The Italian Tradition

Italian classical archaeology has been similar to the German tradition, since the early-nineteenth-century days. Filippo Coarelli (1994) explored the subject and concluded that historical problems and narratives guided classical archaeology on the one hand and on the other stressed cross-referencing and description. Even Marxist-inspired classical archaeology (e.g., Ranuccio

Bianchi Bandinelli, Mario Torelli, Andrea Carandini, and Daniele Manacorda) upheld both tenets. Today, classical archaeology in Italy has been subjected to social theory via Anglo-Saxon influences, but mostly it is the German style of medium range theory of religion studies, economics, or even law studies which are most relevant.

The French Tradition

Classical archaeology in France was established in the nineteenth century as a reaction to German movements. The French established archaeological schools in the Mediterranean in the wake of the German ones, and the main German tenets were also adopted, but the French style came with a reversion of roles. While the Germans searched for Aryans, the French looked for colonizers and civilizers, as if the ancient Greeks were the only early bearers of civilization standards (*la mission civilisatrice*).

Renewal came from the 1960s due to several reasons, most notably French colonial setbacks. The discipline was also concerned with the importation of field techniques, such as the Wheeler grid. Most relevant has been the recent redefinition of the discipline as historical archaeology, as proposed by Étienne et al. (2000). The use of middle range theories from semiotics, religion studies, economics, and others is now much more common, and anthropological issues are also apparent. Again, this move is close to what happened in German-speaking countries and Italy, while a social theory of wider scope is still usually sidelined.

Future Directions

Historical archaeology and classical archaeology developed in completely autonomous, independent, and even contradictory ways. However, they share some major concerns with the role of writing and literary narratives in shaping the understanding of material culture. They also share issues relating to roots, identity, national, and imperial power, as well as how to deal with the other, opposing civilization and barbarism. In recent decades, several scholars have been stressing the usefulness of a closer relationship between all the archaeologies in general and particularly those studying societies using writing, from the Mayas to Egypt, China, and the contemporary USA (Gosden 2004). Even more related are historical and classical archaeologies, for they share a common classical canon but also the criticism of this canon in recent decades. The cross-fertilization of both fields has been going on for a while and promises to grow in the future for the benefit of an informed archaeological approach to ancient and modern societies.

Archaeology and the Emergence of Fields: Maritime

A

Jennifer F. McKinnon
Program in Maritime Studies, East Carolina University, Greenville, NC, USA
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction and Definition

Maritime archaeology in its most basic form is the study of material culture related to human interaction with the sea. It involves the study of ships and shipwrecks, maritime infrastructure, maritime exploitation, maritime identities and landscapes, seascapes, and other types of heritage, tangible or intangible, associated with the sea. Related to maritime archaeology is the study of nautical archaeology which primarily focuses on "the ship" and all technical and social aspects of the ship, whether it is on land, underwater, or extant in a museum. Also related to maritime archaeology is underwater archaeology, which is concerned with the archaeology of sites located underwater, regardless of their connection to the sea; it includes not only shipwreck sites but also aircraft wrecks, sunken cities, submerged indigenous habitation sites and refuse sites. Thus, maritime archaeology differs from underwater archaeology in that its focus can be on wet or dry sites including shipwrecks, ship burials, shipwrecks buried in reclaimed land, maritime infrastructure sites (such as jetties and lighthouses), or shipwreck survivor camps. To further complicate matters, there are more related and overlapping study areas including lacustrine archaeology (archaeology in and of lakes), riverine archaeology (archaeology in and of rivers), marine archaeology (archaeology that occurs in the marine environment), and the list goes on. The development of maritime archaeology is intimately connected with each of these associated study areas through overlapping subjects, methodologies, and theoretical developments and can be difficult to separate when

reviewing its history. Nevertheless, this entry will only cover the development of maritime archaeology as a subdiscipline, and as such, sites and studies not related to human use of the sea will be omitted.

Historical Background

The emergence of maritime, underwater, or nautical archaeology as a field or subdiscipline within archaeology has been primarily linked to the works of George Bass in the Mediterranean in the late 1960s (Bass 1967). His research project was the first underwater excavation of a shipwreck directed by a diving archaeologist. Nevertheless, as stated in the above definition, maritime archaeology is not strictly conducted on sites underwater. Lesser known, or less associated, are the earlier works and publications of a number of individuals and projects that set the pace for conducting maritime archaeology, albeit on land. Beginning in the late nineteenth and twentieth centuries, discoveries of watercraft in tombs and on dry land were investigated by antiquarians and archaeologists alike. Examples of such work include Jean-Jacques de Morgan's (1895) discovery and excavation of Egyptian boats in tombs at Dahshur and Basil Brown and Charles Phillips' team excavation of the Anglo-Saxon ship burial at Sutton Hoo in 1938–1939. While these research projects were not conducted underwater, the site types and subject matter can be considered well within the purview of maritime archaeological studies. The individuals who undertook this early work held university degrees and were trained in archaeological excavation techniques. Further, the archaeological questions asked were consistent with contemporary thought and revolved around the assembly of culture types and culture-histories.

Underwater efforts to recover objects and investigate sites by amateur archaeologists and salvors were also attempted through breath-hold diving, surface-supplied air sources, and diving bells. While these projects are interesting from a historical diving perspective, they contributed little to the development of the discipline other than fine-tuning some of the underwater exploration and recovery techniques which eventually would be used by archaeologists. In contrast, a project that is considered to be the earliest and first state-sponsored underwater archaeological survey took place in Greece at the naval warfare site of the Battle of Salamis by the Archaeological Society of Athens in 1885 (Lolos 2003; Catsambis 2006). Although trained archaeologists directed divers from the surface, this project represents perhaps the very first maritime archaeological survey underwater. The field reports of this survey were only recently found and translated, which leads one to believe that there could be several more of these surprising examples waiting to be discovered.

The development in the 1940s of the Aqua-Lung, a self-contained underwater breathing apparatus (SCUBA), allowed humans to reliably explore the underwater environment. SCUBA provided a vehicle for explorers, antiquarians, and, indeed, later archaeologists to begin freely examining material culture located underwater. For example, in the 1950s and 1960s, French and Italian SCUBA divers worked under the direction of archaeologists on wrecks at Grande Congloué, Cape Dramont, Île du Levant, Mahdia, Spargi, and Albenga (Atti del II Congresso 1961; du Plat Taylor 1965; Roghi 1965; Bass 2011). These surveys may not have included full-scale archaeological excavation or even diving archaeologists, but they certainly fulfill the criteria considered appropriate for conducting modern "deepwater archaeology" projects in which archaeologists on the surface direct activities underwater.

Arguably, one of the largest recovery projects to take place in the history of maritime archaeology was the raising of the Swedish warship *Vasa* in 1959 (Cederlund and Hocker 2006). This project set the pace for large-scale excavation and recovery projects, and for the next few decades, a number of large shipwrecks were recovered such as the warship *Mary Rose* in England and Dutch East India Company vessel *Batavia* in Australia. Alongside these projects being conducted underwater, equally significant

maritime archaeological work was being undertaken in Scandinavia. By employing a cofferdam to allow submerged shipwrecks to be excavated as terrestrial sites, the Skudelev project involved the excavation of six Viking ships by Ole Crumlin-Pedersen and Olaf Olsen in 1962 (Crumlin-Pedersen and Olsen 1978).

What began with the untethered exploration of the underwater environment using SCUBA quickly developed into full-scale treasure hunting. Sites around the world were being destroyed in search of elusive treasure contained within shipwrecks. By the 1960s, legislation to protect underwater cultural heritage was being developed to prevent looters from destroying early shipwrecks. In fact, the Western Australian Government passed one of the earliest pieces of heritage legislation in the world in 1964 (Nash 2007: 3), which would ultimately become the model for Australia's *Historic Shipwrecks Act 1976*. By the late 1960s and early 1970s, several large-scale maritime archaeological projects were under way including excavations of the seventeenth- and eighteenth-century Dutch East Indiamen wrecked off of Western Australia, the fourth-century BCE Kyrenia ship in the Mediterranean, sixteenth-century Basque whaleships in Red Bay (Canada), and Spanish Armada wrecks in the USA and Caribbean. However, by this time, fewer were being directed from the surface as more archaeologists were conducting their own research on the seabed. John Goggin (1959–1960: 350), considered a pioneer in underwater archaeology for his work in freshwater springs in Florida (USA), was never more true when he stated, "it is far easier to teach diving to an archaeologist than archaeology to a diver!"

Another major step forward was the 1972 introduction of the *Journal of Nautical Archaeology and Underwater Exploration*, the first journal specifically devoted to the subdiscipline. Soon after, academic departments at universities in various parts of the world established programs dedicated to maritime archaeology; some of the early examples include those at Texas A&M University, University of Haifa, St. Andrews University, and East Carolina University. This was the beginning of what would become a proliferation of specialty degrees and would produce most of the first round of heritage managers and academics focusing on the subject.

Once maritime archaeology was a named degree or specialization within university archaeology and anthropology departments, it earned the status of a subdiscipline. While some speculate that this was a potential negative impact in the development of the discipline as a whole and that maritime archaeology should be taught alongside and in conjunction with the broader field of archaeology (Flatman 2008), others reveled in its acceptance and even benefitted from the newly developed specialty programs. As of 2011, there are no fewer than 15 academic departments around the world that teach maritime archaeology, and in nearly every country that borders on water, there is a maritime archaeologist working. Indicators of the success of the subdiscipline include the 2006 introduction of a second journal dedicated to the field of maritime archaeology (*Journal of Maritime Archaeology*) and a steady increase in the number of jobs in maritime archaeology.

Today, the field is so broadly focused and diverse, if it were not for the definition of "human and sea," it would be difficult to describe it adequately. No longer is it necessary to be a diver to specialize in maritime archaeology because there are an equal amount of maritime-related sites being investigated on land as there are underwater. From lighthouses to shipwreck survivor camps, maritime archaeology is just as at home on the dry edges of the sea as it once was underwater.

Key Issues/Current Debates

Perhaps one of the most pervasive issues within the field of maritime archaeology is the need to protect underwater cultural heritage from those who wish to profit by selling, bartering, or trading associated material culture. Treasure hunting and looting of all forms is an offense maritime archaeology has battled from its inception. Even with the 2009 ratification of the UNESCO Convention on the Protection of the Underwater Cultural

Heritage, the security of underwater heritage remains unstable in many countries around the world, and permits are issued regularly for treasure hunting endeavors. Public education and pressure to change laws at the State party and international levels are two areas where maritime archaeologists may contribute to correcting this problem. As Bass has so rightly pointed out, "[t]he distinction between archaeology and treasure hunting is misunderstood by far too large a part of the population" (Bass 2011: 14). Thus, education and engagement of the general public in maritime archaeology is critical. The media, from magazines to newspapers and television, is a powerful tool that has yet to be capitalized fully by maritime archaeologists and is a substantial key to educating the public about the difference. Treasure hunting is not profitable based on its "finds"; rather, it profits from selling a dream to unsuspecting investors. If there are no investors, there is no treasure hunting. Further, pressure to enact or change laws from individual and collective groups of maritime archaeologists, such as the Advisory Council on Underwater Archaeology and the Australasian Institute for Maritime Archaeology, can also provide protection to underwater cultural heritage. Through writing letters, lobbying governments, and providing technical assistance to developing countries that are often preyed upon by treasure hunting ventures, such groups are winning small battles. The enforcement of the UNESCO Convention on the Protection of the Underwater Cultural Heritage will be a huge leap forward in terms of managing and protecting underwater cultural heritage, but there is still much work to do on the local front.

Another related and key issue within the field is that of managing underwater cultural heritage. As more threats arise and budgets are restricted, maritime heritage managers are forced to find new ways of managing and protecting sites through survey (to locate sites), investigation (to identify sites and threats to them), and long-term monitoring (to ensure they are protected and to record changes over time). Over the last 10 years, large-scale excavation and recovery projects have waned. These projects are being replaced by in situ surveys, investigations, and monitoring, which involve leaving sites as they are rather than disturbing or recovering material culture. The current buzz word in the field is in situ preservation and conservation, and while most authors have pointed out that UNESCO defines in situ as a "preferred" method of management rather than the "only" method, it still weighs heavy on the minds of maritime archaeologists. Part of the issue with the concept in situ revolves around a lack of definition and principles for conducting in situ conservation and preservation. Because the field of in situ research is largely driven by conservation scientists and the results disseminated in conservation journals and conferences, there appears to be a lack of communication between the researchers (conservation scientists) and end users (maritime archaeologists and managers). A study conducted in 2009 of practitioners revealed that many were unaware of what constitutes in situ preservation and conservation techniques and were therefore unwilling to consider in situ as part of their management practices (Ortmann et al. 2010). Thus, an area of research and discussion for the future of maritime archaeology will undoubtedly be focused in the coming years on in situ methods and their use. Closer collaboration, scientific investigation, and on-site application, as well as wider dissemination of results, may contribute to a better understanding of in situ practices.

The management and investigation of archaeological sites beyond the reach of divers, such as deepwater or remote shipwrecks, is an area of growing interest. Advances in technology are facilitating access for not only the archaeologist but also the novice and in some cases the treasure hunter. Deepwater sites often fall under the jurisdiction of State bodies, and practitioners are charged with managing sites that they cannot in fact view or visit. Additionally, deepwater wrecks require sophisticated and expensive equipment, large platforms for operating that equipment, and in some cases lengthy cruises to access the sites. Finally, because these sites are further out to sea, they are not protected under State legislation. Thus, they are unprotected from disturbance and

treasure hunting. So how are these issues negotiated? The answers to accessing and investigating these sites may lie in the cooperation with large organizations, such as marine institutes that conduct geophysical, biological, or oceanographic research. However, partnering with groups who possess the technology and ability to access such sites will only allow the archaeologist to arrive at the site; the next issue is how to conduct archaeological investigations on deepwater sites. The same concern that others raised about archaeologists conducting archaeology from the surface in the 1960s, again, rears its head. Can proper archaeological work be conducted on sites that can only be accessed remotely? And perhaps more importantly, what types of research questions can be adequately addressed? Can questions that count be asked of sites where little ability exists other than to collect samples for identification of site type, function, and possibly cultural affiliation? Are basic archaeological site plans reconstructed though remote photography and video contributing to our knowledge about the people and culture behind the sites? Answers to these questions are currently being debated among academics and practitioners (Adams 2007). There are no easy answers to these questions; however, the issue exists and is not one that will disappear or even decrease in complexity.

A final key issue that has rippled beneath the surface and is occasionally communicated relates to interaction of indigenous peoples with the sea and the investigation of archaeological sites closely associated with these activities. Until relatively recent times, maritime archaeology has primarily focused on classical and historic period sites. Ships, lighthouses, boatyards, jetties, and harbors were typically constructed by historic culture groups. Thus, maritime archaeologists have given relatively little attention to sites and regions of the world where an indigenous population had/has an intimate connection with and use of the sea. These sites are overlooked primarily because they fall within the realm of terrestrial archaeologists who focus on indigenous sites. However, maritime archaeologists can contribute greatly to this area; the key lies in collaboration. Maritime archaeologists are trained to look at the specific "maritimity" of a site or object (Tuddenham 2010). When viewing coastal and inland sites, our first questions involve the location of the nearest port or how far inland a river is navigable. Answers to questions about access to goods and trade networks often involve waterborne travel rather than overland travel. Maritime archaeologists understand seasonality, maritime subsistence, and boat-building technologies. Some researchers have begun to collaborate on projects related to indigenous knowledge and use of the marine environment and the importance of watercraft in migration, but the work is slow to develop. This area of research could contribute not only information about past and present use of the sea but also indigenous claims of tenure and sea rights. Maritime archaeologists and their research have the potential to contribute to relevant modern social issues in the areas of indigenous maritime tenure in the coming years.

Future Directions

From its inception, an overwhelming obsession with shipwrecks, method, and technology has left the subdiscipline of maritime archaeology unbalanced. Just as developing methods for finding and recording shipwreck sites underwater were a necessity for the field to grow, so was the need to align research with current intellectual and theoretical discourse within the broader field of archaeology and anthropology. Unfortunately, the field's practitioners failed to accomplish this second phase, and a period dominated by historical particularism characterizes most of the early work. However, all is not lost; in recent years, the battle to overcome the historical-particularist approach is well under way. A perusal through journal articles, books, and websites demonstrates that maritime archaeologists are actively engaging in greater intellectual and theoretical debates with the disciplines of archaeology and anthropology. The investigation of more terrestrial maritime sites including landscape and seascape studies

and shipboard material culture are areas in which theoretical discussions are occurring.

Another future direction that is vital to the field of maritime archaeology is that of public engagement. This has never been more important than now when the world's economy is flailing and budget cuts are severely impacting State bodies, granting organizations, and education funding. The public write letters to those who make the laws, vote for the laws, and, ultimately, are for whom maritime archaeology is practiced. Engaging people in all levels through consultation, volunteerism, and eventually to the final product of publication and dissemination of results is an area in which maritime archaeology can expand. And it appears to be making progress; with successful organizations and programs such as the Nautical Archaeology Society in the UK, the Florida Public Archaeology Network in the USA, and the Museum of Underwater Archaeology online, the public is being brought into the fold. There remains, however, room for improvement such as involving and interpreting sites for the non-diver and producing stimulating media products to rival exploration and treasure hunting ventures. In an age of video games, simulation technology, and mobile applications, maritime archaeology offers a veritable and endless source of public entertainment and education.

Archaeology and the Future

Cornelius Holtorf and Anders Högberg
School of Cultural Sciences, Linnaeus University, Kalmar, Sweden

The Future as a Research Subject in Archaeology

The future has seldom been an object of archaeological study even though there are some very profound and deep-reaching links between past, present, and future (Holtorf and Högberg 2015; Högberg et al. 2017). In particular, archaeologists and others dealing with the archaeological past are negotiating the future in two ways. On the one hand, they are studying long-term change. Patrick V. Kirch, for example, suggested once that an archaeology of prehistoric global change investigating the effects of uncontrolled human population growth on environmental degradation ultimately leading to sociopolitical crises can make a contribution "to the future of this planet" (Kirch 2004: 23). The historian Daniel Lord Smail used a long-term perspective of prehistoric human evolution to discuss the deep history of the human brain and its past, present, and future in order to discern what is fundamentally human today and how this understanding might be constituted in the future (Smail 2008). In environmental studies, models of prehistoric climate change and long-term human impact on the environment have been used to discuss past climate variation and possible future trends (Rockström et al. 2009). And recently, by investigating economic history drawing on archaeobotanical and ethnoarchaeological data, Amanda Logen discussed how food insecurity in Ghana emerged as late as the nineteenth century in connection with the introduction of market economies and colonial rule, revealing the future potential in certain areas "to maintain a high level of food security even during severe, prolonged drought" (Logen 2016: 11). Some archaeologists, such as Ian Morris (2010), have even been making explicit attempts at forecasting future developments based on historical analysis and reasoning.

On the other hand, archaeologists are managing human legacies as heritage. Archaeologists work to preserve places, environments, and associated values and knowledge for future generations. But although it is not far-fetched to claim that the future will differ from what we are used to in the present, in managing archaeological heritage, most assumptions about the future do not build on an understanding of how the future will be different from today. Instead, planning processes imply that key aspects of heritage and contemporary society will not change greatly in the future. This tendency to assume a likeness of present and future corresponds to the way people, as individuals, "expect to change little in the future, despite the fact that they have changed a lot in the past" which in turn "bedevils their decision-making" (Quoidbach et al. 2013: 96).

A recent study (Högberg et al. 2017) investigated how professionals within the heritage sector conceptualize the future in their daily work. Based on interviews with professionals working in the heritage sector in Sweden, England, and internationally, it emerged that very few in the heritage sector have professionally thought deeply about the future. A few heritage professionals do not see a need to consider a longer future in their work at all. Most heritage professionals see the need but cannot easily express what they think about the future they work for other than that it will be the time of our children and grandchildren. Hence, there is a paradox in large parts of the heritage sector. Professional heritage practice focuses on the future as a fundamental premise of the work, as acknowledged in many heritage policy documents (Högberg et al. 2017). Yet this future remains implicit in daily heritage practice which operates in a continuing present. It is expected that future generations will look back gratefully at the work done by the heritage sector today.

Based on these results, it is easy to agree with Spennemann (2007a, b) that the future is often little more than a popular "catch phrase" in relation to heritage, while present practice remains firmly focused on the past and the present. But

we cannot be certain that archaeological heritage will always be valued as a source of historic information or as a symbol of a collective past nor that the various heritage objects and landscapes we preserve will be appreciated by future generations for the stories they can tell about the past. We cannot know for certain how or if future generations will perceive, use, and receive benefits from heritage. Many, if not all, heritage objects have been reinterpreted regularly during the time of their existence. Indeed, the very notion of a heritage worth preserving in systematic fashion for the benefit of future generations has only existed for a few 100 years. Like archaeology, contemporary conservation ethics do not stand outside history but are firmly situated within it (Holtorf 2015).

From Historical Consciousness to Future Consciousness

For the reasons given, the future is an important research subject for archaeology. But archaeology is also itself firmly embedded in time. The discipline as such is part of history; it emerged about two centuries ago in a specific social and cultural context (Thomas 2004) and is in a constant process of change and development (Mizoguchi 2015; Pikirayi 2015). Archaeology is a particular way of creating information, knowledge, and meaning of specific objects and spaces in the present, and it will not exist forever. We cannot assume that current archaeological ways of making sense of the past will persist. By the same token, the notion of (archaeological) heritage is undoubtedly part of our history and, thus, part of the future human heritage in itself (Holtorf 2012).

It is by understanding change over time and in particular by understanding changing perceptions of past and future that archaeology can contribute to contemporary decision-making processes. In particular, the way humans make sense of pasts and futures in the present is important for how they situate themselves in the present. Arguably, the ability to understand the present as a consequence of change over time and the way we plan for the future separate us from other species. These issues have often been discussed in relation to the notion of historical consciousness (e.g., Rüsen 2001).

The concept of historical consciousness refers to the meaningful relations between past, present, and future that govern – and are established and reproduced – in uses of the past. Historical consciousness is thus a concept that refers to the underlying thought structures that generate meaning when a particular historical perspective is actualized and given significance in the present, implying certain consequences for the future (Rüsen 2001). Similar thought structures can also be actualized and given significance by particular perspectives on the future, with certain consequences for how we see the past. Therefore, historical consciousness could equally well be called future consciousness. The concept of future consciousness is in line with so-called critical future studies which are framed by a constructivist and self-reflexive approach (Miller 2011; Poli 2015). Just as it is possible to analyze historical consciousness from the way it manifests itself in uses of the past, future consciousness can be analyzed from the way it manifests itself in perceptions and uses of the future.

A graphic (Fig. 1) illustrates how processing of the past and the future in the present can be understood. Society exists in the present, in its *Now*. Assumptions about different futures create various perceptions of the future in the present. The *preferred future* is what different stakeholders would like to happen and therefore varies between individuals and communities. The *probable futures* are what will likely happen. Since the probable futures are not one but many futures, it is likely that several stakeholders can agree on them. *Plausible* and *possible futures* are what could happen, respectively, of what might happen. These are not specific futures but rather theoretical possibilities deriving from certain detectable trends and movements in the present.

In analogy with the future, various interpretations about the past create different perceptions of the past in the present. Within the wide and almost infinite spectra of things which have taken place in the long-term history of *possible pasts*, i.e., what today can be interpreted out of all events having

Archaeology and the Future, Fig. 1 Future consciousness: schematic illustration of how interpretations of the past are transformed through the needle's eye of *Now* into assumptions of the future. Crucially, this is a "rolling now" constantly moving along the axis of time as the future becomes present and the present becomes past. Figure by Anders Högberg, inspired by graphics of Stephan Magnus (https://adventurefuture.wordpress.com/2012/04/16/six-rules-of-forecasting/) and Anthony Dunne and Fiona Raby (2013: 5)

taken place as well as what we imagine having taken place over time, a selection is made of *plausible pasts* and a *preferred past*.

These pasts all have to be processed in our present, the *Now* in Fig. 1. As sand in an hourglass has to flow from one container to another through a narrow passage, time is constantly flowing through an ever-changing present. By passing through that narrow passage, the needle's eye comprising our present, the past is transformed into various assumptions about the future, i.e., future scenarios.

As we move the needle's eye of the *Now* along the timeline in Fig. 1 back into the past or forward into the future, the shape of the figure will always stay the same. Every past and future present has specific limits and possibilities on how people understand their specific *Now* in relation to their interpretations of the past and their assumptions about the future.

Future societies will have their own perceptions of past and future resulting in their own preferences in a future *Now* and will, therefore, need to make their own decisions. We need to recognize that future societies will have their own views not only of the past but also of the future.

Reinterpretation and indeed change of information, knowledge, and meaning over time is not a problem to be eliminated but a basic condition of human development over time which we need to understand and take on board. We have to allow for future *Nows* to create their own knowledge to act upon and for future human beings to act as creative and innovative creatures able to generate information, knowledge, and meaning that we cannot even imagine today.

These issues have been explored in relation to specific cases. In 2007, visitors to the Swedish History Museum in Stockholm were invited to select contemporary objects as "future memories." Together with attached labels containing stories about their perceived significance in the present, the objects were first formally recorded and registered in the museum's database and then permanently "incavated" inside the museum courtyard in holes that had previously been excavated by other visitors. The intention was to inspire reflections in the present on objects from the past and in the future, how we remember previous times, and how future generations will remember us. But the project was also meant as a provocation for the museum and heritage sector to reflect on their current practices, not least

concerning the benefits they will offer to people in the future (Wahlgren and Svanberg 2008).

In relation to "nuclear semiotics," i.e., the challenge of long-term communication about final repositories of nuclear waste over thousands of years, a recent project concluded that it is by understanding changing perceptions of past and future, and indeed of change over time more generally, that archaeology allows us to make better decisions concerning the sustainable preservation of information, knowledge, and meaning in a long-term perspective (Holtorf and Högberg 2014a, b, c). Here archaeology contributed to nuclear semiotics by showing that we cannot be certain that nuclear waste will always be seen predominantly as hazardous waste posing a threat to humanity nor that its radioactivity or other physical properties will always be its most significant property. For example, results from research on life histories of north European megaliths show that meaning and uses of these have changed significantly over time (Holtorf 1998). Similarly, the meaning of nuclear waste and its final repositories is likely to change over time. Although radioactive substances can be very dangerous, for example, when they enter the food chain or are used in dirty bombs, the locations of their storage or disposal do not have to be seen forever as areas of deadly threats but may, given time, be transformed into altogether different things. This is not to deny or ignore real dangers posed by radioactive material to future generations but more to look at these dangers in the present from a different perspective on their possible future context. Arguably, the best chance to transmit knowledge and information in the long-term is thus to keep knowledge alive in the short and medium terms, inviting future generations to interpret and use these sites in their own way.

Futures Unimagined: Future Thinking for Archaeology

Future thinking in archaeology can also be described in terms that relate future consciousness and different perceptions of possible, plausible, preferred, and probable futures to specific strategies of action in the present. The future in our actions may be optimized, unpredictable, or unimagined (Miller 2011; Miller et al. 2013; Poli 2015).

The notion of an *optimized future* is commonly applied in heritage management, especially in relation to the current conservation ethos. All planning builds on what happened in the past and what that implies as to what will happen in the future. The basic idea is that in a system with fixed rules and resources, it is possible, through planning and calculation, to steer certain parameters in order to reach a desired outcome. Many in society are engaged in optimizing futures in this way. They create futures through assessments, predictions, visionary perspectives, planning, explicit goals, strategic thinking, risk analysis, implementation, optimization of results, evaluation, analysis, and impact realization (see, e.g., Tonnquist 2012). However, methods that focus on cause and effect as a basis of predictions lead to a projection of recognizable trends and patterns of the past onto the future. In this way, the future is effectively colonized by extrapolating contemporary assumptions drawn from analyses of the past. As a consequence, the future comes to represent our image of the past. This is especially evident when the selection process in the present that governs which heritage should be conserved for the benefit of future generations depends on how well this heritage can represent our understandings of the past.

The *unpredictable future* is a result of external circumstances which cannot be foreseen in detail. This kind of future is often managed with the help of probability analysis. The notion of an unpredictable future encourages planning as a way of improving our ability to respond to those events that we cannot predict. A good example is current discussions on exactly how climate change will affect the preservation of heritage sites (e.g., Barthel-Bouchier 2013).

In contrast, the notion of an *unimagined future* comprises what we cannot even imagine today: futures that have not been discovered yet, i.e., aspects of our present that need to be investigated much more before we will be able to express futures that have not been thought before. Following this strategy, we need to improve our ability to

create futures that are not a mere mirror image of the past but that challenge current patterns and trends and thus help us create a better society. Key terms here are innovation and discontinuity. In practice this future is difficult to realize because it is about "futures unimagined and hence a present that does not *yet* make sense" (Miller 2011: 25). The challenge for archaeology and heritage management lies in finding ways in which an unimagined future can successfully inform specific strategies of action in the present.

The optimized future draws on the past to make predictions. The unpredictable future anticipates known risks based on what might occur but cannot be foreseen in detail. Both strategies of action are thus based on society's collected knowledge – what is known or expected to happen, extending the present into the future. They determine the limits of what people anticipate to change in the future. But these limits are not themselves expected to change; they are locked in present-day historical consciousness.

The unimagined future differs from these two strategies. It is also based on society's collected knowledge, but instead of projecting the present onto the future, it investigates what we need to know, imagine, and change in order to create futures which would be desirable but which we cannot think at the moment. Drawing on the notion of an unimagined future means finding new ways of understanding the present in order to strengthen our capacity of innovative thinking. Such thinking aims at taking advantage of an unknown future rather than becoming its victim. It helps us to question dominant perceptions in the present of what is right and proper. This strategy, then, is not about predicting the future but about creating capacity in order to be able to deal with a continuously changing world, by allowing us to use the unimagined as a resource in the work that we conduct to bring about the future.

Conclusions

Archaeologists and other professionals working in the heritage sector as well as their institutions should start thinking in more depth about the future (see also Högberg et al. 2017). Which future(s) are we working for? What are our aims concerning those futures? How can we be confident that our work will make a difference for the better? In order to understand how archaeological heritage can be part of that response, we need to go beyond, for example, bemoaning the fact that some sites will be negatively affected by rising water levels. Instead, we need a thorough discussion of how archaeology can develop theoretical thinking about the future. We also need to discuss how archaeology, heritage, and the past may be useful resources in making a positive impact on humans inhabiting that future.

Archaeologists should not only promote historical consciousness but also future consciousness: both forms of consciousness are essential for the ability to appreciate the interconnections between past, present, and future. The continuing discussions about long-term communication strategies concerning final repositories of nuclear waste can provide archaeologists with inspiration. The lack of substantial engagement with future issues in heritage management and heritage studies contrasts sharply with the commitment that we have come across among professionals in the nuclear waste sector addressing concerns that lie in the long-term future. There are a number of comprehensive studies (e.g., Trauth et al. 1993; Buser 2013) discussing how to communicate with our descendants, or indeed other forms of intelligent life that may exist in many thousands of years ahead, so as to prevent that they inadvertently expose themselves to radiation. In these works, consideration is given to the likelihood that no single language or alphabet of the present, including symbolic codes, will be easily understood and that even ways of interpreting and engaging with material markers or other media we may leave behind may not match our own customs and expectations.

Besides occasionally offering risky forecasts, archaeologists should give similarly detailed attention to the long-term effects of their own practice: How do specific perceptions of the future inform contemporary practices? Which impact on the future can, and indeed should, archaeology and archaeological heritage have? Can we

reasonably expect certain things of future generations? Which futures are we talking about anyway? Asking questions such as these will build capacities for archaeology to be more creatively and effectively connected with the pressing social, economic, political, and ecological issues of our time.

Archaeology and Time Travel

Cornelius Holtorf and Bodil Petersson
School of Cultural Sciences, Linnaeus University, Kalmar, Sweden

Bringing the Past Back to Life in the Present

Time travel can be defined as an embodied experience and social practice in the present that brings to life a past or future reality. What is most characteristic of time travel is therefore the possibility in contemporary society to experience the presence of another time period (Fig. 1).

Time travel to the past has become a widespread practice and desire among many age groups, with present society increasingly offering relevant opportunities. Prominent examples of popular forms of time travel in contemporary society and popular culture are living history, historical role play, reenactment, and first-person interpretation, often associated with cultural institutions of various kinds. But time travel also occurs, among others, in literary fiction, movies, TV docusoaps, advertising, themed environments, and, last but not least, the rapidly improving virtual realities and computer games. Time travel is thus linked to a wide range of contemporary phenomena. It occurs not only within and through people's minds and bodies but is equally the result of specific social practices that support and indeed allow time travel experiences, especially a range of leisure activities, cultural tourism, and the heritage industry as well as shopping, reading, watching movies and TV, playing games, and more and more the use of augmented and entirely virtual realities.

Over the past few decades, all these different forms of time travel have become increasingly significant in tourism, entertainment, and education, especially museum and heritage pedagogy (see, e.g., Hjemdahl 2002; Hunt 2004; Thompson 2004; Hart 2007; McCalman and Pickering 2010; Kalshoven 2012; Hochbruck 2013; Samida 2013;

Archaeology and Time Travel, Fig. 1 Lejre, Land of Legends. A modern family temporarily living in the Iron Age. (From the photo archive of Holtorf: 2011)

Kruse and Warring 2015; Willner et al. 2016; Holtorf and Petersson 2017).

People have of course long been fascinated by imagining other periods and bringing them to life in some form, as reflected, for instance, in people taking part in historical processions, consuming historical novels, strolling through open-air museums, or interpreting historic sites. Certainly there have been staged performances of historic events in the Roman period and during the Middle Ages. Sites like Pompeii and finds like bog bodies and ice mummies, in particular, have long been seen as "frozen in time," material objects in which you can meet the past face-to-face as it were. For certain, a desire for time travelling, retrieving the past, or envisioning the future is a cultural theme that goes back some two centuries and has occupied authors and scholars alike, among them H. G. Wells and Arthur C. Clarke who inspired many (see Lowenthal 2015: chapter 2).

The academic study of time travel goes back at least to the 1980s. Important starting points for the existing academic appreciation of the phenomenon of bringing the past back to life in the present are Jay Anderson's (1984) discussion of *Time Machines: The World of Living History*, the classic account of *The Past is a Foreign Country* by David Lowenthal (recently revised, 2015) and the first volume of Raphael Samuel's (1994) study of present-day *Theatres of Memory*. Since then a fair amount of relevant work has been published, as indicated not the least by the references given earlier. Concerning the history of historic open-air museums, Sten Rentzhog (2007) provided a comprehensive discussion from their beginnings with Skansen in 1891 up until the introduction of virtual time travels. Particularly interesting in this context is Bodil Petersson's (2003) research about archaeological reconstructions and their attempts at recreating different periods of the past. She found that in the reconstructed Stone Age, travellers find harmony with nature, simple technology, and social equality; the reconstructed Bronze Age holds social hierarchies, fertility rituals, and some ecological thinking; the reconstructed Iron Age appeals to some with homemade food, clothes, and small-scale village life; the reconstructed Viking Age offers seafaring, long-distance trade and warfare, and even world peace; and the reconstructed medieval period, finally, presents the time traveller from the present with markets and cultural festivals, clear social roles, and knights' tournaments.

The Significance of Time Travel

In our age, mainly thanks to new technologies and increased demand, time travel has acquired a new level of popularity and societal significance. Time travel does not only represent a new tool for research, but it also manifests the changed role of material culture in archaeology generally. In experiences through which the past comes back to life, we can observe that bodily sensations and evocative narratives substitute for the study and analysis of material evidence in understanding the past, so that archaeology may no longer be self-evident as the discipline par excellence of things (Holtorf 2014). Now things may merely take the role of props facilitating larger stories and experiences.

Time travel arguably represents an alternative way to approach the past in current society in general. Whereas the most common approaches to the past have been foregrounding either knowledge and insight or critique and politics, now credible experience and sensual immersion feature large. Time travelling is directly linked to the lives and bodies of individuals in the present. It may begin at 8 p.m. on a particular TV channel. We are living in the present, but we are free to enter the past now! This perspective is neither about knowledge of human history and evolution nor about a critical assessment of those who write history, but about our imagination and embodied experience. Key notions for the way in which the past becomes meaningful through time travel include credibility and engagement. The past does not have to be genuine in the sense that it once "really" happened, but it needs to be credible as an authentic experience about a past that *could* have happened. Credible pasts are largely reliant on trust. We trust pasts either when they correspond closely to the past we already know, that is, our expectations, or when they are vetted by

experts whom we trust. Time travel does not demand a particular intellectual attitude toward either past or present but instead a readiness for an embodied engagement with different realities, involving both body and soul. Time travel is about getting immersed in another world, assuming the perspective of somebody actually living in that world, involving all the senses.

The dynamic of time travel lies in a constant oscillation between life now and then. On the one hand, the time traveller never leaves the present and remains the person she is, with all the associated baggage in the form of world views, preconceptions, and personal life histories. On the other hand, the time traveller is leaving that present and being transported to another reality governed by different norms and open to all sorts of fantasies and behaviors that may not be associated with our lived present.

Some of the most significant aspects of time travel are based on knowledge that is next to impossible to ever be (re-)gained in a scientific way. Sensual perceptions, embodied experiences, habitual behaviors, emotions, dreams, and not knowing what historically "came next" have been crucial to life in any period, but archaeologists and others cannot easily reconstruct these dimensions from the evidence available today. It is hard to avoid imposing our own responses to these issues on other periods and thus constructing the past as an extension of the present. But arguably an extension of the present is precisely what is desired as, ironically, many time travellers ultimately seek to find themselves in the past (Fig. 2; Petersson 2009)!

Is Time Travel Actually Possible?

But how can another period, whether past or future, become "present" and a subject of embodied human "experience"? Is time travel merely a clever metaphor, or can it be said to describe a social and cultural reality? Initially, it seems obvious that a discussion of time travel carried out while being firmly based in the present can only be either pure magic or a product of the imagination, thus being unreal and contra-factual. No one can *actually* travel either into the past or into the future, in the same way you can travel to another country.

However, it is essential to ask what is meant by travelling in time "in reality." The statement that actual time travel, leaving present-day reality, is impossible employs a commonsense definition of reality: empirical, physical reality. According to this definition, *real* is everything physical, large or small, which we can empirically investigate, whether that may be an atom, a brain, or an ancient sword. Within contemporary physics as we know it, there is no time travel allowing us to leave our own empirical reality – although there certainly are some other anomalies regarding time such as the fact that it slows down when travelling at high enough speed. Physical reality is however not the only way to understand reality, and it may not even be the one that is most significant to

human beings. Reality might also be defined as the combination of human experiences and social practices. Reality, in this alternative view, is whatever humans experience during their lives and practices as social beings. This definition of reality is particularly pertinent here as it implies that all reality is partly virtual and all experienced and practiced time travel is real. According to this view, past and future are not physical realities distinct in time from our own but themes that contribute to shaping specific human experiences and social practices in the present (Fig. 3).

Time travel has a lot to do with the presence of *pastness* (and indeed futureness – but our discussion will in the following be restricted to pastness). Pastness is the contemporary quality of an object to be "of the past." This quality comes with the perception of something to be of the past and has thus little to do with actual age (Holtorf 2010, 2013, 2017).

The concept of presence has in recent years attracted a considerable amount of research within a range of academic disciplines, including IT science, psychology, performance studies, communication science, and media studies (Hofer 2016; Lombard et al. 2015). The defining notion of presence is a perception of non-mediation or immediacy, that is, a perception of "being there," even though the experience may actually be mediated to a considerable extent. For example, a sophisticated virtual environment provides a sense of presence when it convincingly suggests that you are visiting an actual place or meeting other people rather than looking at one or more digital screens, which is what you actually do. As with encountering such virtual places or people, whether or not pastness in time travel is perceived as non-mediated will depend on the extent to which:

(a) The past reality presented is consistent and coherent.
(b) The audience is familiar with the medium and willing to suspend any disbelief.
(c) The audience's senses are persuaded through rich and vivid impressions, i.e., the underlying technical sophistication creating a sense of immersion.
(d) Pre-understandings and expectations of the audience are matched.
(e) The audience is involved and engaged in a meaningful way (inspired by Lombard and Ditton 1997).

Provided these conditions are satisfactorily met, a perceived presence of pastness and time travel that brings the past to life becomes entirely possible. At its best, the time traveller experiences what is known as "period rush" or "magic moments" when another period suddenly comes to life. It is emerging realities such as these that have now begun to be taken seriously and investigated in a variety of social sciences and humanities, especially in the historical disciplines.

Understanding Time Travel

Time travel can be conceptualized and different dimensions of time travel distinguished along the two axes representing the degree of lived experience and degree of collectivity, respectively (Fig. 4). The past may be played and performed or lived and experienced, collectively through

Archaeology and Time Travel, Fig. 4 A framework for understanding contemporary time travel and its various dimensions. (Based on Holtorf 2012)

group effort or separately in individual projects. Many forms of time travel combine playful and sincere aspects and have individual as well as collective dimensions.

In some time travel, the past is a kind of game, a playful and sometimes superficial entertainment drawing on well-known imagery and behavior commonly associated with the past. Playing the past can be as amusing and enjoyable for the individual participant assuming a historic role as for audiences of public performances that may be offered in a spirit reminding of carnival. Under the sign of "PLAY," the past is being staged somewhat tongue-in-cheek, and concessions to the present are willingly made for the sake of added fun.

In other time travel, the past is a lived reality, a heartfelt and sincere attempt at effectively representing the past in the present. Recreating past life may be achieved as a personal life project by effectively choosing to embody another person or collectively through the systematic acquisition of expertise and academic insight. Under the sign of "LIFE," the past is serious and given a new authenticity in lived experiences or accumulated knowledge of the present.

Rehabilitating Anachronism

It is generally accepted that living history, historical reenactment, and virtual reality cannot bring the past back to life *as it really was*. The significance of this truism to present-day time travel is however a matter of some discussion, even among those participating (Hart 2007; Hochbruck 2013; Samida 2013). Some commentators dispute that any time travel could ever be entirely genuine and authentic; however, much attention is given to getting the historical facts right. Time travel, therefore, always remains flawed and problematic as anachronistic ("against time") and inauthentic, to some extent misleading audiences about past realities, effectively representing stereotypes or fantasy and appropriating the past for some contemporary purposes. But others contend that all representations of the past originate in the present and are constructed for a specific purpose and in a particular context; historical research appropriates the past too and does not depict the past *as it really was* either. So why not use embodied experiences and the imagination to satisfy our historical curiosity?

Among archaeologists and historians, anachronism is usually conceived of as something genuinely inappropriate because it falsifies the representation of a particular period of the past by mixing different time periods in historically impossible ways. Two areas of practice with a special concern of avoiding anachronism in the name of authenticity are historical music and the use of language in literature, film, and theatre (Haynes 2007; Lowenthal 2006). The ambition here is usually to try to avoid more recent soundscapes or words/languages/expressions in favor of ancient and thereby "authentic" ways of using sound and language. It might be very disturbing for an audience to hear modern language spoken within a setting supposed to be Roman or Viking. In this genre, the efforts are more related to those within archaeology and history, in which the goal is to avoid "inauthentic" interpretations that are too dependent on present circumstances.

The charge of anachronism can also apply to a modern person seemingly entering the past and "living" the past. Impressions gained by our own senses may deceive the critical minds of historians and archaeologists (although sight is usually excluded). There is a real danger that arranging seemingly historical settings with contemporary traits makes the present integrated in the past so much that it really feels familiar and understandable. This is deceptive and takes away from the past the possibility to represent an alternative to the present. But according to another perspective, the deliberate use of anachronism shows that however we interpret the past – or the future – it is formed in the present. In the early twenty-first century, we have often been looking for evidence of female power, queer perspectives, diversity, sustainability, and the role of children and healthcare in the past. All these aspects were highly relevant and/or debated at the time, and their discussion in relation to the past could therefore make the past relevant, too. This is well established in art and literature and can equally apply to history and archaeology too.

The lessons possible to learn from actual time travel to the past do not necessarily provide actual benefits to historical scholarship. This will be especially true in cases where time travels lead to destinations that in any case are partly or entirely fictional and thus lack a solid factual basis. Should time travels to the lost worlds of Atlantis or Valhalla enjoy the same exposure in society as those to Classical Athens or Ancient Rome? Is it worrisome or encouraging when several thousands are visiting the Swedish region of Västergötland in the "footsteps" of the fictional historical character Arn derived from Jan Guillou's best-selling novels and subsequent movies (Mattsson and Praesto 2005)? Should the state provide public-service time travels to carefully vetted destinations with particularly desirable learning outcomes? Can time travel actually lead to inappropriate destinations? Fictional or semi-fictional pasts may be inappropriate destinations – but are not all pasts brought to life to some extent fictional and dependent on partly fictional assumptions?

Even plain and methodical anachronism can be a very rewarding and illuminating tool helping us to understand the past in the present. Places where methodical anachronism may occur are traditional museums, open-air museums, museum centers, and the so-called educational centers as well as at archaeological and historical sites sometimes named heritage sites. Methodical anachronism might also appear in books and other scientific or popular publications, or in the practice of ancient handicrafts using old-fashioned tools and techniques. Historically inspired anachronistic events may include markets, theatres, games, and tournaments. They can be arranged by, for example, schools, universities, nonprofit organizations, societies, gaming communities, and web communities.

Anachronism has deep roots in human practice, both conscious and unconscious. It can be interpreted as a human practice of translating between times and thereby an effect of human awareness of time. Artists have long made active use of anachronistic references, crossing periods at different levels of awareness of this practice:

Archaeology and Time Travel, Fig. 5 Medieval church painting from Härkeberga in mid-Sweden. (Photograph: Bodil Petersson 2010)

unconscious, semiconscious, and fully conscious use of anachronisms. In church paintings from the medieval period in Scandinavia (*c*. 1050 onward) and throughout the Middle Ages, people depicted are dressed in clothes contemporary with the painter for recognition by the audience, in this case visitors to church ceremonies (Fig. 5).

Two genres that make active and conscious use of anachronism are theatre and literature. Plays are often transformed into contemporary settings. For example, Greek dramas or Shakespearian plays are remodeled into the twenty-first-century society of Western Europe, or opera plays such as Mozart's *The Magic Flute* (*Die Zauberflöte* in German) are reshaped for more recent, present, or even future settings. The stories are constantly being reinterpreted and modernized. This can give renewed actuality and credibility to important thoughts and actions in plays and texts from the past, even if they were created and performed many hundreds, or even thousands, of years ago. As archaeologists and historians, we should, instead of fearing anachronism, do more like theatre and literature by using anachronism as a tool for creating actuality through time (Petersson and Narmo 2011; Petersson 2017).

Discussing Time Travel

An important question about both storytelling and time travel in contemporary society is about the criteria that should be used to evaluate different stories and time travel experiences. The answer will in part depend on which specific example we are talking about, but are there certain qualities that are inherently more valuable than others (see Fig. 6)? Are stories and time travels good or bad depending on the degree to which they are generally most persuasive? Academically true? Emotionally touching? Aesthetically pleasing? Commercially viable? Ethically acceptable? Or politically correct?

Another important question is who determines, and on which grounds, which pasts are historically well grounded and appropriate to be accessed by time travel and which are not. There are different reasons why dark and troubled pasts may be inappropriate for time travel. For example, should people travel in time to experience Nazi extermination camps such as Auschwitz-Birkenau and bring the early 1940s back to life there? Should such a trip be encouraged to remember the victims and keep the memory of the Holocaust

Archaeology and Time Travel, Fig. 6 The annual munch-ball match, refereed by the Pope, during the Medieval Week in Visby: genuine engagement with medieval heritage, good storytelling played out, luring tourists to Gotland, or nonsense in bad taste. (Photograph: Cornelius Holtorf 2003)

alive? Or should it rather be discouraged or even prohibited out of respect for the victims' families and their legitimate expectation of respect? How realistic and educational could it be anyway and what sort of people would be attracted to embody the German perpetrators? How appropriate is time travel as a medium for bringing to life such dark periods? Arguably, even the negative sides of history have to be brought back to life. Indeed, many time periods are littered with mass murder and all sorts of terrible things that ought to be witnessed but at the same time must not be trivialized or left out. Perhaps we have a particular duty to travel to unpleasant destinations as we may in that way take important lessons and emotions back to present reality. The problem is what lines you have to draw, and how to enforce them, over and above the obvious need to prevent time travellers from committing actual crimes.

Another important issue is whether there are any risks or dangers in time travel, or in other words what a critical perspective on time travel may have to contribute. Time travel makes for embodied experiences that are potentially very persuasive and memorable as well as enjoyable and even delightful. Arguably, American Civil War reenactments constitute a proliferation of reactionary politics glorifying White American resistance and sacrifice while failing to express sufficient distance to racism and slavery. Another issue of concern is that many forms of reenactment, especially those relating to conflicts and battles, are dominated by heterosexual men. Much reenactment builds on traditional gender roles that contradict present-day ideals to achieve gender equality and ensure equal opportunities.

In 2013, on the 200th anniversary of the Battle of the Nations at Leipzig in Germany, a particularly elaborate reenactment of the battle was staged. In response to the widespread glorification of wartime and soldier life, a group of injured and demoralized soldiers was supposed to disturb the picturesque image of the battle (Haude 2015). These defeated soldiers and their behavior throughout the area of reenactment reminded the audience of those events associated with the Battle of the Nations not otherwise remembered in reenactments: illnesses and injuries, the forced quartering of troops, plundering, raping, widespread destruction, and general misery among the population. Indeed, what is the message of playing war in battle reenactments of various

periods from antiquity to the twentieth century when this occurs at the same time that many thousands of refugees seek asylum from the nightmares of currently ongoing wars and the resulting chaos and human suffering in contemporary wars?

Another interesting and important question is whether or not time travelling should in fact be seen as a form of escape from the present: dressing in period clothes, a changing of daily routines, and adopting a different identity and value system while reenacting historical scenes, or closely observing all of that, make participants and audiences temporarily suspend and forget their ordinary lives (Hunt 2004: 399). Arguably, time travels are spaces of sensual and embodied action and adventure where the alienated modern city dwellers can release some of their frustrations. Tourists travelling in time can experience a heightened feeling of being present "here and now" that many are longing for. In these ways, time travel may compensate for the deficiencies of present society rather than contribute to social improvements, thus rendering it inherently conservative in society. However, it could also be argued that time travel is not an escape from present society at all, but rather its fulfillment. According to the logic of the Experience or Dream Society, in which we may be living, the proliferation of experiences and dreams, for example, in the form of time travelling, corresponds to its true character. The critical task at hand would then lie in correcting any possible negative outcomes of time travels, not their abolishment. Indeed, time travel experiences of other realities may also popularize social utopias and instill in people very concrete models of alternatives to present society, so that their social impact might be rather revolutionary. All these issues warrant further discussion in the future.

Conclusions

Time travel experiences and associated social practices have become ubiquitous and popular, in some cases replacing more academic and less anachronistic ways of packaging the past for popular consumption. Knowledge-oriented and critical approaches to the past are still around, but embodied engagements in time travel have gained a lot of ground in many contexts.

If reality is defined as the sum of human experiences and social practices, all reality is partly virtual, and all experienced and practiced time travel is real. In that sense, time travel experiences are not necessarily purely imaginary. Time travel facilitates the presence of pastness (or futureness) in people's lives, emerging from contemporary human experiences and associated social practices and making a direct contribution to human lives and social practice in the present.

Our discussion brought some of the implications and problems associated with the ubiquity and popularity of time travelling into view. They include the question by which criteria, and certainly by which institutions, time travels and anachronism should be assessed and evaluated for the benefit of society. Are there time travel destinations that we should be warned of or prevented from reaching because of ethical concerns? Does time travel invariably promote the original dominant values (e.g., concerning race, sexuality, and gender roles) of the periods of destination? And precisely what are we to make of the often-commercial overtones of some time travel opportunities? Finally, there is a continuing debate on whether time travel is inherently conservative because of its escapist tendencies, whether it might instead be considered as a fulfillment of the contemporary Experience or Dream Society or whether time travel might even popularize utopian visions that could make people want to work actively for a different society.

For all these reasons and ongoing considerations, time travel is a legitimate and timely object of study and critique involving scholars associated with any discipline investigating the past or with heritage studies, tourism studies, social anthropology, sociology, cultural economics, or film and media studies, among other fields. Time travel needs to be placed into the larger societal

context it deserves as a particularly significant way of bringing the past back to life in the present.

Archaeology as Anthropology

Cristóbal Gnecco
Department of Anthropology, Universidad del Cauca, Popayán, Cauca, Colombia

Introduction and Definition

Archaeology, it has been said, is one of the four subdisciplines of a larger discipline – anthropology – the other three being bioanthropology (formerly known as physical anthropology), linguistics, and social/cultural anthropology (a double adjective that honors both the British and American traditions). This account, however, largely only reflects the American context. In most other parts of the world – notably in Europe, where the "disciplines (or subdisciplines)" were born – the two have been separated thematically, pedagogically, and administratively. But even in the Americas, where the linking of archaeology to anthropology is rarely disputed, their explicit relationship is strained, and it could be argued that the stated relationship does not really exist; further, it has been utterly distant for the most part, so much so that in spite of an avowed nearness and their contributions to the same thematic field, they successfully ignore each other. Their closeness or distance is a direct function of their relationships, separated or in tandem, with colonialism, nation-building, and, nowadays, with post-national multiculturalism. Yet, what anthropology means to archaeology and vice versa is important to their destinies in postmodern times.

In considering the relationship between archaeology and anthropology, however, more commentary is required to clarify the discussion that follows. Archaeological interpretations have *always* used cultural data – especially as professionally produced by anthropologists – in order to give meaning (functional and symbolical, for the most part) to "things" and "sites" through cross-cultural analogies; although the latter were used intuitively and in a very relaxed way for decades, archaeologists have spent much effort to refine and control their use. In this regard, the intimate, unidirectional relationship of archaeology with anthropology is quite evident and needs no further development. Other stories can be told in terms of their mutual or separate articulation to wider agendas and purposes, political and otherwise; the following is the story I chose to tell.

Historical Background

The origin of anthropology is tied to the European colonial expansion of the nineteenth century. Baffled by the weird behavior of the very peoples they sought to colonize and exploit, colonial governments rapidly understood that the best way to an efficient government was the understanding of the locals. The anthropological understanding of the "savages" thus emerged as a condition for better governments. Archaeology is older. It was born in the eighteenth century to feed the historical imagination of a recently created modern entity: the national society. Anthropology appeared to normalize the "other" of modernity (the "savages" located in an ontological exteriority), while archaeology tamed an undisciplined time vector built upon objectification, universality, and progressive temporality – modern time, that is. Their common European birth was thus not coterminous and arose in different contexts: while the latter provided the teleological and monoethnic temporality the recent nation-states needed, the former was geared to the administration of colonized peoples in Asia and Africa. Although canonical definitions have it that both were meant to deal with "men" as a cultural being (one in the past, the other in the present), in Europe and elsewhere they performed quite disparate functions. The story is different in the Americas, where archaeology was part and parcel of a larger field called anthropology.

The relationship between the two varies with place and time. In Europe and most of the world, it hardly exists or is merely formal. In the Americas – and, to a lesser extent, also in Australia and New Zealand (Harry Allen, personal communication) – it may be argued that they share a common genealogy. While archaeology in Europe wrote about the "savages" as proto-

selves – in evolutionary terms, the primitive that eventually evolved into the civilized Westerner – in the Americas and elsewhere "savages" were written about as the "other" external to modernity. In European countries, the denegation of coevalness to their own pre-civilized "savages" was a function of teleology: they were not part of modernity because they truly belonged to past times; their rhetorical existence (their presence in archaeological narratives built upon "true" relics) and their eventuating into modern selves (their presence in national histories) were proofs of the elapsing of progressive time. In the Americas the "savages" as "other" (the paradigmatic Indians) were not part of that story: they did not evolve into the civilized self. As if that were not enough, in Latin America the appropriation of some indigenous achievements – carefully selected as to mimic European civilization (gold work, domestication of crops, monumental architecture, religious life, centralized governments, even writing-like systems) – by national storytellers, all members of elites that despised the Indians and considered themselves "white," was a brutal paradox. Archaeology became the notary public of the passing of pre-European societies; it legitimized the disappearance of the Indians (something of the past), and it paved the road to *mestizo* national ideologies.

Such was the basic difference between the colonial centers of power and the colonized areas in terms of storytelling. Indeed, in Europe, anthropologists were producing information from and about the "savages" while archaeologists were mere citizens proudly elevating their own heritage; in their colonies of Africa and Asia, European archaeologists were delving in the pleasures of antique hunting. In the Americas, Australia, and New Zealand, archaeologists and anthropologists worked toward a similar goal, nation-building. For these reasons, archaeology in Europe and its colonies was not part of anthropology. In contrast, archaeology played a different role in the Americas where it took part in the normalization of contemporary "savagery." Archaeology and anthropology in the Americas were one and the same; their relationship was a pure brand of the apparently odd complicity between modernity and colonialism. While anthropology set to normalize the "savages" through indigenism, archaeology normalized them by imposing a new temporality (that of civilization) and by using their chosen civilized traits as national symbols – the latter was especially true in Latin America. In short, both were modern disciplines designed to modernize "savagery" through the production of national imaginations.

While in most parts of the world archaeology and anthropology have silently traveled along different paths, it is not surprising that in the Americas their relationship has preoccupied archaeologists – anthropologists, aware of their theoretical sophistication and the nuances of ethnographic renderings, have despised the rude empiricism of their disciplinary colleagues to whom they pay little attention. Archaeologists felt – and, to a large extent, still feel – that their subdiscipline was there to serve a higher anthropological purpose, the holistic understanding of humankind, through a painstaking spatial and temporal ordering of ancient things left in the ground. They did so, basically, by providing the long-term data that evolutionary typologies about society needed to fill temporal gaps. Yet, afraid that the relationship was drifting toward a mere departmental cohabitation with no epistemological articulations and seeing in anthropology a model to be followed, Philip Phillips (1955: 247) wrote what became a famous dictum, with lasting consequences: "American archaeology is anthropology or it is nothing." The anthropology Phillips was referring to was one of a kind – objective and disciplined by scientific protocols. The mirror archaeologists were looking at was that of a nomothetic and universalist science. Later on, Lewis Binford (1962) outlined even clearer relations through the use of the key term *explanation* ("the demonstration of a constant articulation of variables within a system"), the hinge that would articulate the disciplines dealing with "men" as cultural beings amenable to scientific scrutiny.

Anthropology was chosen as a model for archaeology due to an unreflective legacy that stressed a common origin, but it soon became a burden. A subservient dependence of archaeology

to anthropology was resented by many, especially in terms of theory, so much so that a strong appeal grew for archaeology to develop its own conceptual machinery. The scientific program widely adopted since the end of the 1960s found necessary to maintain genealogical ties with the mother discipline but building its own theoretical and methodological apparatus (understanding that the technical attire was already at hand) as a way to elevate archaeology to full maturity. An iconic paper in this regard was written by David Clarke (1973) – a British scholar, to be sure – celebrating the loss of innocence of archaeology at the expense of almost ignoring anthropology. Confident that even its own "general theory" was reachable, archaeology decided to follow its own path. The decision was not surprising; although heralded by British scholars who came from a non-relational tradition, it rapidly took roots and sealed the abandonment of the last traces of its functional relationship with the nation – and of its relationship with anthropology! Archaeology locked itself in a scientific, meta-real world, away from contemporary preoccupations such as collective history and identity – the very stuff anthropologists were dealing with. For scientific archaeologists, the field that still linked them to anthropology, although by sheer instrumentality, was ethnoarchaeology, widely promoted as a contact with *living peoples* but which was simply devoted to producing information for the translation of statics (the archaeological record) into dynamics (the operation of cultures).

The wave of reflection and criticism that beset anthropology after the 1970s (which occurred due to the mounting accusations of its complicity with colonialism) eventually impacted archaeology. Although never as agonizing as in anthropology, the critical move took the form of meta-disciplinary inquiries: the complex relationships with imperialism, nation-building, "othering," and capitalism came to the fore, in many cases, for the first time. The disentanglement of such relationships brought archaeology close to anthropology because it touched the nerves of the contemporary world. It also showed that archaeological products were constructed in social milieus and were thus social facts, inherently political. Politics are thus a recent archaeological preoccupation that has been engaged in several ways. Most archaeologists practice politics the multicultural way: politically correct while going public, they celebrate their proximity to "otherness" (still an academic object) but are careful not to mingle excessively and to safeguard their epistemic privileges – repatriation being the best example because it does not compromise the integrity of the discipline but allows archaeologists to get closer to the "other." A growing minority genuinely strives to reconcile knowledge and power, surgically separated since the end of the nineteenth century by positivism, and has made archaeological interventions politically conscious at all levels; in doing so, it follows anthropology's estrangement from colonialism by siding with and giving voice to the very people it used to study for governmental purposes; it became anticolonial and even antimodern. Discontent with a discipline that was a favorite proxy of modernity *qua* colonialism, a sector of anthropology started to think and act critically and independently, so did many archaeologists who refused to be functional to the rhetoric of multiculturalism.

Yet, most anthropologists work within the current social and political order, providing the epistemic means through which "otherness" is administered by the rhetoric of diversity, not least through the ongoing promotion of development. A more academic approach has seen the adoption of a constructivist agenda that portrays culture (and its weaving of the social fabric through identity) as situational, fluid, conjunctural, and strategic, thus castigating cultural primordialisms, especially ethnic. Alternative anthropologies have emerged, though, building upon previous political commitments. They stress collaboration in research (establishing research priorities from the local up) and account for non-Western cosmologies; the latter are not any longer seen as exotics awaiting cultural translation but as meaningful renderings of life on their own. Further, the widespread academic anti-essentialism is countered by a critical, at times sympathetic, understanding of the politics of identity. Archaeology is also plural in contemporary contexts. Two or three decades of

multiculturalism have altered its face. If archaeology had a clear relation with nationalism during its modern phase, in its house now reign disorder and confusion; if it formerly administered discourses partly designed to deal with others located outside of modernity, it now ignores what kind of discourses it administers when those others are no longer the exteriority of modernity but a constitutive interiority of multicultural societies. Many archaeologists, especially those in countries suffering aggressive capitalist expansions, satisfy market needs through cultural resource management (CRM) or cultural heritage management (CHM), becoming commodities themselves and undertaking their work according to a legalistic and vertical conception of heritage. Scientific archaeologists often fustigate CRM/CHM practitioners, arguing that their scholarly standards are piecemeal, if not unaccounted for; committed to an increasingly cumbersome liaison with science, they are unlikely birds in multicultural lands – decontextualized fellows who insist on courting a narrative monopoly already lost to other interested parties. Before that fact, a growing number of archaeologists have forged a curious approach that mixes a bit of old positivism with a pinch of new constructivism; they label it *public archaeology*, a fine multicultural product that accommodates the old tenets of archaeological practice to the changing multicultural contexts. Still others have embarked on different paths, seeking to forge alternative archaeologies – this is the case for disciplinary practitioners working through collaborative research agendas with local constituencies and/or via indigenous activism. Alternative archaeologies, though, still retain a metaphysical and ontological disciplinary core. For that reason, alternatives to archaeology are being casted world round with the aim of engaging non-Western conceptions of time, space, matter, and relations.

Key Issues/Current Debates

Several books (Gosden 1999; Gillespie and Nichols 2003; Garrow and Yarrow 2010; Shankland 2012) and a wave of professional symposia over the last few years show that the relationship between anthropology and archaeology is a matter of renewed interest. The main meeting points, sometimes intertwined, are ethnography and materiality; Ingold (1993) would add time and landscape to the list, but I will not explore them here given that they have received much less attention. Nor will I discuss the still widely held idea that archaeology is uniquely positioned to provide long-term data for the anthropological understanding of cultural practices or, as in the case of *applied archaeology*, for the implementation of successful past technologies in current contexts – such as pre-Hispanic raised field agriculture in tropical places in South America. The archaeological access to the long-term (also called the *distant past*) would account for variations and changes (but also continuities) not available to the theoretical and methodological machinery of other social disciplines. The understanding of adaptations and extinctions (their causes, consequences, and advantages) has been usually mentioned as the basic field to which the privileged archaeological gaze can contribute. However, such a contribution is hampered by a widespread rejection of uniformitarianism and by a simple tautology: archaeological models based in anthropological data are used to inform anthropological interpretations.

Ethnography

The theoretical, metadisciplinary lookouts that archaeologists build to have a better view of their own work (and, many times, to elude their responsibility) are usually removed from practice, as if their reflection about general, past concerns protect and isolate them from the very processes to which they contribute, intentionally or not. The genealogies of particular archaeological trajectories – such as the relationship between the discipline and nation-building – have proven their utility to uncover its social/contextual character. Yet, they lack an essential ingredient: the ethnographic present in which we are all trapped and which forces us to confront our work in real time

more than as the unavoidable legacy of faraway forebears. Such a limitation appears to be being overcome in recent times. Ethnography now appears as a common ground for archaeology and anthropology, so much so that a recent review paper (Hamilakis 2011) calls it "a multitemporal meeting ground" for them both.

New relational approaches, variously called "ethnographies of archaeology" (Edgeworth 2010), "archaeological ethnographies" (Hamilakis 2011), or "ethnographic archaeology" (Castañeda and Matthews 2008), "use ethnographic methods to try to understand the *cultural practices of archaeology* itself" (Edgeworth 2010: 54); their philosophical core is constituted by relations and meanings between beings, not things. They share a concern with the effects of archaeological activities (excavation, exhibition, curation, dissemination) upon local publics and, conversely, with how local publics engage archaeology and its diverse discursive objects. To use a time-honored archaeological expression, they document their own activities in situ: the archaeological *site* is thus elevated to a constructed place where the very materiality of the social and the political unfolds (the long-lasting effects of archaeological discourses – their articulation with national, regional, or subaltern agendas, for instance – are not the focus of their inquiry). Through reflexivity and self-criticism, they seek to understand (a) how archaeologists produce knowledge as situated and positional subjects, (b) how different publics relate to it (ironically, selectively, opposingly), and (c) how archaeological representations are deployed (and many times countered).

Archaeology may find in the ethnographic gaze a bountiful source of reflexivity about the observer/observed dichotomy. For decades, archaeologists disdained ethnography (that weird activity performed by anthropologists, uncomfortable bed partners to whom they didn't talk, with whom they didn't share) only to consider it now a novel way to connect past and present. Archaeological ethnographies are not akin to the ethnoarchaeological activities scientific archaeologists were so accustomed to. In spite of optimistic and condescending appraisals that posit it as a forebear of archaeological ethnographies, more often than not ethnoarchaeology reinforces the logocentric gaze, avoids intersubjectivity, and subdues multiplicity; its almost exclusive purpose is to produce dynamic cultural data for interpreting static archaeological information, bypassing or ignoring the lives of the peoples they judiciously study, those *mobile objects* whose sole role is providing information useful for archaeological interpretations; the people thus studied are just unveiled objects, measured, disciplined. But away from ethnoarchaeology, archaeologists and local communities can engage in new kinds of relations, meaningfully built around interactions of lives and beings and intersubjective understanding – the very meaning of ethnography, anthropologists notwithstanding (Fabian 1990).

Materiality

A widespread and shared idea is that archaeology's specificity, more than anything else, lies in its expertise about artifacts, especially if they are ancient. For most of archaeology's history, artifacts were inert, exterior, and silent things geared to mediate between culture and nature; although resulting from human interaction, they were utterly reified. Yet, due to the holistic approach to culture championed by the scientific program, artifacts began to be considered more widely and interactively as an important part of *material culture*; the use of *material* as an adjective of *culture* (but not vice versa) signaled an important change whereby social relations entered the otherwise sealed and autonomous realm of artifacts. An important consequence of this move was that archaeology engaged in related discussions with other fields (philosophy, economy, history) and pitched its tent in time slices and topics formerly banished; such is the origin, for instance, of historical archaeology and its more recent offspring, archaeology of the recent past. Joining forces around material culture with other disciplines, archaeology began to speak about commodities,

consumerism, and the constitution of social personas. Such an interdisciplinary endeavor is behind the creation of material culture studies (e.g., Buchli 2002). Part of the same move, the so-called anthropology of technology (Lemonnier 1992) brings archaeology and anthropology together by deploying ethnographic observations upon cultural practices around *techné*. Those observations downplay economic reductionism as a means to understand human choices regarding technical and technological options; instead, they show that such choices are often dictated by powerful drives that cannot be explained by functional criteria. The ethnographic, non-reductionist approach adopted by the anthropology of technology has humanized the mechanism inherent in studies designed to understand technological organizations, the Anglo rendering of the French *chaîne opératoire*. A related field of inquiry, from which archaeologists have largely profited, aims to reconstruct the social life of material objects (Appadurai 1988), mostly through the lens of political economy – the very reason that explains why things are thus considered in their mercantile phase as commodities. Another notable area of research along these lines put museums in the forefront because they are the iconic places for direct, bodily interactions between the public and archaeologically produced objects.

Not long ago, archaeologists brought theories of agency to bear on material culture, thus showing how humans position themselves actively toward "things" and how the latter participate in the production and reproduction of social life; the participation of things, however, does not occur as beings (as relational accounts would have it) but still as fetishicized and reified objects. Agency is accorded to humans, not to things. This fact underscores that most material culture studies are undergirded by modern ontological precepts whereby "things" and humans remain rigorously separated as much as mind and matter. For that reason, the term *materiality* is now preferred by those who favor processes and events and, perhaps more importantly, who think that objects can be disentangled from their modern ontological cradle. An exciting alternative has thus emerged, one that engages other ontologies in which life and the world are conceived and acted upon relationally, understanding materiality through its embeddedness in a web of living entities (Haber 2009). It is linked to the work of several individuals and traditions, basically in the social studies of science (e.g., Isabelle Stengers' *cosmopolitics* and Bruno Latour's *symmetrical anthropology*) and anthropology (e.g., Marisol de la Cadena's *multiontologies* and Eduardo Viveiros de Castro's *multinaturalism* and *perspectivism*).

Future Directions

Optimism is mounting among many archaeologists about the rapprochement with anthropology through ethnography, so much so that the editors of a recent volume devoted to the issue stated that "we foresee a time when ethnographies of archaeology such as these (which describe the social context, local reverberations, or political economies of archaeological ideas or objects) are considered just as significant to the field of archaeology as is excavation or artifact analysis" (Hollowell and Mortensen 2009: 8). However, there are powerful reasons why we should not celebrate so soon. Two contemporary conditions further the cleavage between archaeology and anthropology by solidifying the self-isolation of the former and by hampering its political edge: (a) its accommodated relationship with multicultural policies, especially those dictating political correctness and the commoditization of otherness, and (b) by embracing CRM/CHM projects, whereby disciplinary practice is geared to the needs of development.

The multicultural face of archaeology is pitiful. A "reformed" establishment is happy to share what it cherishes most with previously marginalized parties: disciplinary epistemic coherence. The gains are numerous: it keeps practicing archaeology as it was laid out by modern standards (it changes nothing of its metaphysical fabric); it does so in public (generously); it feels more

democratic (by sharing); it gets closer to what it used to call the "savage," appeasing her/his demands while convincing itself that disciplinary nearness is tantamount to spatial, temporal, and cultural coalescence. All in all, however, archaeology keeps spreading the fruits of enlightenment and gets other (local) actors to participate in institutional spaces created to control the definition and management of disciplinary principles.

The intimate relationship of archaeology with capitalism – as expressed in its provision of empirical data for supporting progressive temporality – has been augmented by the expansion of CRM/CHM worldwide. Its impact is so pervasive that a significant number of archaeologists work for that growing market – in Brazil, for instance, where the situation is distressing, that number may be as large as 90%. In doing so, they have abandoned any possible intervention in contemporary issues in order to dance to the rhythm of money. CRM/CHM is even producing profound curricular transformations (something achieved by no other event in the history of the discipline): new undergraduate programs – characterized by their short length (normally no more than 3 years) and their technical emphasis – are being created to mass-produce archaeologists to fulfill the contractual needs arising from aggressive capitalist expansions (transport infrastructure and mining are the most salient). In the process, the already weak ties with anthropology have been severed. The result is an utmost estrangement of archaeology from anthropology by severely abating the struggle for social justice, including engaging alternative social/historical cosmologies, and curtailing a critical stance toward the global order; by fueling the conversion of heritage and the past into commodities, long ago denounced; and by an overt complicity with market mandates, effectively diminishing the possibility for the discipline to rebuild its metaphysical and ontological apparatus, already clearly hierarchical and neocolonial. What archaeologists dreamed for decades (their independence from anthropology) seems to have been finally achieved by the most gruesome of means: their ultimate surrender to capitalism and the multicultural order. Although this complex stage would demand an attentive introspection, it seems that just the opposite is happening: most archaeologists are now more impervious to critique and self-reflection than ever before. They feel fine with their multicultural concessions; besides, the CRM/CHM money that flows through the inner circuits of the discipline is of such magnitude that they don't want anything or anyone disturbing their comfort. For these two main reasons (multiculturalism and CRM/CHM), most archaeologists are happy to preserve their privileges – cognitive and otherwise. This perverse situation has produced complacency and silence.

The future relationship between archaeology and anthropology is thus subjected to different forces. One is centrifugal and pulls them apart: it does so by accommodating to multicultural and capitalist needs. Another force is centripetal and brings them closer, sharing concerns in a convergent, alternative platform where modern metaphysics and ontology are at stake. In this regard, archaeological ethnographies can produce the collapse of disciplinary self-referentiality, the demise of its closure. They can also offer intersubjective experiences as the loci of knowing, which cease to be a function of a methodological prescription, as the canon of modernity established, to be the result of relationships between subjects who strive to bring closer different worlds; such proximity can open up alternatives of life and action that truly are alternatives to a Western cosmology. The intersubjective space facilitated by the ethnographic encounter entails the dismissal of objectivism in archaeological and anthropological discourses. In the ethnographic encounter, but also in the establishment of horizontal and participative relationships that seek to eliminate distance (between observer and observed, researcher and object of study, the West and the rest), archaeology meets anthropology anew. This encounter, not accidental or bureaucratic any longer but deliberate and militant, is the stage for a new morality that cannot be found solely within disciplinary borders (stubbornly patrolled to

preserve epistemic privileges) but which will more likely arise from an engagement, simple and non-hierarchical, with lives built and being built outside Western mandates.

Archaeologists are keen to talk about the past – well, that is what they basically do. They are not so keen to talk about the future, a temporal horizon far removed from their trade. It is not surprising, then, that it has been precisely an anthropologist who has ventured into the shifting grounds of prediction to imagine what archaeology and anthropology are going to look like four decades from now. For Tim Ingold, a concern with relatedness (instead of anthropocentrism) and the persistence of life (instead of preservation) will define a common agenda:

> Between Archaeology and Social Anthropology, then, there is no longer any difference of principle. They have, in effect, converged upon a science of life whose overriding concern is to *follow what is going on*, within dynamic fields of relationships wherein the forms of beings and things are generated and held in place... [Thus] the *archaeo-* of archaeology and the *anthropo-* of anthropology have lost their former appeal... [and archaeology] has become an anachronism for the subject that still goes by that name has long since lost its association with antiquity. It is not that archaeologists have ceased to dig down for evidence of past lives, any more than ethnographers have ceased to participate in the lives that are going on around them, in what we call the present. But they have dropped the pretense that what is past is any older, or more ancient, than the present, recognizing that the occurrences of the past are not deposited at successive moments while time moves on, but are themselves constitutive of that very moment. (Ingold 2010: 160)

Archaeology Data Service (ADS)

Julian D. Richards
Department of Archaeology, University of York, York, UK

Basic Information

Archaeology Data Service
Department of Archaeology,
The King's Manor,
University of York,
York YO1 7EP, UK
Email: help@archaeologydataservice.ac.uk
Web: http://archaeologydataservice.ac.uk/

The Archaeology Data Service (ADS) was established on October 1, 1996, with the mission to preserve, catalog, and describe digital data generated in the course of archaeological research and to facilitate its reuse (Richards and Moore 2015; Richards 2017). These activities are mutually supportive as unless digital data are actively curated, they will not be available to future scholars and unless researchers are going to reuse the data, there is little point in expending effort attempting to preserve them. Preservation is therefore inseparable from dissemination and publication (Fig. 1).

The ADS was set up as one of five disciplinary-defined services within the Arts and Humanities Data Service (AHDS) (Burnard and Short 1994). It developed from a successful proposal from a consortium of university departments of archaeology and the Council for British Archaeology, led by the University of York where it is hosted within the Department of Archaeology. Initial funding came from the Joint Information Systems Committee (JISC) and the Arts and Humanities Research Council (AHRC). From an early stage, the ADS also received external funding from a variety of other UK organizations, such as Historic England, and via commercial archaeology projects, reflecting the diverse nature of the archaeological sector. The ADS provides ongoing support for digital preservation and reuse, for research, learning, and teaching for archaeology and the historic environment sector. Depositors are required to pay a one-off fee, at the point of deposition, based upon the ADS charging policy (Richards et al. 2010). Access to data, however, is free to all. The source of the data must be acknowledged, and copyright is maintained by the data depositor. The ADS takes a non-exclusive right to distribute the data and to take steps to preserve it. All data archives are given a permanent digital object identifier (DOI) under the auspices of DataCite (http://datacite.org/). The ADS is a member of the Digital Preservation Coalition (http://www.dpconline.org/) and follows the Open Archival Information System (OAIS) model for the preservation of digital data (ISO 14721: 2003). In 2010 it was awarded the Data Seal of Approval (https://www.datasealofapproval.org/), and in 2012 it received the DPC's Decennial Award for the most outstanding contribution to digital preservation in the last decade.

Major Impact

Archaeology and the historic environment sector are in a special position in that much data creation results from the destruction of primary evidence, making access to data all the more critical in order to test, assess, and subsequently reanalyze and reinterpret both data and the hypotheses arising from them. Over the years, archaeologists have amassed a vast collection of fieldwork data archives, a significant proportion of which remain unpublished. Access to data, even those which are published, is often difficult or inconvenient at best. The ADS works with national and local archaeological agencies and those research councils involved in the funding of archaeological research to negotiate deposition of project data. This includes data derived from fieldwork as well as desk-based studies. The types of data involved include text reports, databases (e.g., related to excavated contexts or artifacts), images (including aerial photographs, remote sensing imagery, photographs of sites,

Archaeology Data Service (ADS), Fig. 1 The Archaeology Data Service homepage, April 2012

features, and artifacts), digitized maps and plans, numerical datasets related to topographical and subsurface surveys and other locational data, as well as reconstruction drawings. By 2017, the ADS provides access to over 1.3 million metadata records for the archaeology of the British Isles, over 40,000 unpublished fieldwork reports (the so-called gray literature), and over 1100 individual project

archives. The economic impact of the ADS has been the subject of an independent assessment (Beagrie and Houghton 2013). The ADS is also working with European and other international bodies to develop a worldwide e-infrastructure for archaeological research (Aloia et al. 2017).

Archaeology in the Enlightenment

Roderick J. McIntosh
Department of Anthropology, Yale University, New Haven, CT, USA

Introduction

The late seventeenth century and much of the eighteenth witnessed the birth of an intense curiosity among Europeans in the ancient lives and products of peoples occupying the territories of modern western European nations. At this time one saw a continuation of the Renaissance obsession with the art and values of the classical world. In a few, exceptional cases, this curiosity was molded into something approaching a systematic form by Enlightenment-informed projects of cataloging a country's or colony's cultural and natural resources. Sadly, the activities subsurface that resulted from this curiosity was more often little more than unsystematic plunder. It would be fair to say that virtually no archaeological research, in the sense we today understand archaeology (i.e., the total and fully documented recovery of all artifacts, features and human modifications to the landscape, and the critical interpretation thereof), was conducted during the period (1690–1789) that was embroiled in the intellectual ferment known as the Enlightenment.

Yet three key concepts of the Enlightenment still frame debates about archaeological theory in the present. The learned of Europe and the English colonies earned liberation from a servile obeisance to the established political and clerical order by the universalizing canons of science – empiricism, trust in sense perception, and the freeing of human consciousness from ignorance and received doctrine. History was conceived as a predictive science that was fully an equal to the natural sciences because of an abiding faith that all humanity was borne of a common ancestor, with implications for present prehistorians who ask by what methods and authority we can comprehend unrecorded motivations in the past. Lastly, the Enlightenment's signature publication, the *Encyclopédie*, elevated the humblest tool to a probe for comprehending the intellectual status of its craftsman maker, however remote in the past. One of the enduring legacies of the Enlightenment is the general acceptance that archaeology is the study of the remains of past people's actions upon a world as socially constructed and perceived – understanding of which can be empirically derived and is not obscured to the outsider by an inner logic (manual of translation for the meaning of behavior) forever hidden.

Definition

The Enlightenment celebrated scientific society as the highest moral end of history, with the promise that the historical sciences (eventually including archaeology) could reveal moral laws and practical means to increase human happiness.

Key Issues

There is some irony in writing about archaeology in the Enlightenment. Arguably, there was no archaeology practiced (with one or two informative exceptions). Yet, it is also fair to say that three currents of Enlightenment thought converged to give us the fundamental questions we ask of all prehistoric data. It is a commonplace to say that all archaeologists can do is to use fragmentary and ambiguous material evidence to make statements about how peoples in the past acted upon the world as they perceived it. Put another way, the intellectual history of archaeology has been the search to comprehend unrecorded motivations. Were the actors upon the ancient stage much like us, such that we can recreate their motivations in our mind? Or were they playing to a script that is untranslatable to an audience from another time, another society?

These questions would have had no meaning to those who thought about past peoples during the previous medieval or even early modern periods. Post-Enlightenment, these same questions became core to archaeologists' understanding of the world (and continue to split philosophers of the social sciences into partisan camps).

In order for archaeology to be something other than an academic vanity, there must be a basis for cross-cultural and deep temporal understanding of what motivates people, in the past and present. How that cross-cultural understanding is derived may be a matter of strident dissent (e.g., witness the ongoing debates between processualists and post-processualists). The fact is that this question – how can we, at a remove in time and often of an alien culture, comprehend unrecorded motivations in the past? – is central to the archaeologist's enterprise and means that we are all children of the Enlightenment. But here we have to separate the intellectual task of archaeology from the data retrieval and processing task. To the vast majority of those who dug into ancient monuments and remains during the roughly 100 years of the Enlightenment, little knowledge was gained. So let's deal with this issue first.

Thomas Jefferson's 1784 excavations of Virginia burial mounds (arguably the only systematic, if "unintended" archaeological excavation conducted as part of the Enlightenment project) were undertaken to gather data to counter the argument of degeneration of North American animals, indigenous peoples, and their institutions. The nitty-gritty of the excavations techniques could hardly be called up to modern standards; however, the description and recording of what was found and in which stratigraphic context were surprisingly good. If we can agree that modern

systematic data collection starts with a question, a question that generates implications about patterning of the material remains, patterns that are, in turn, observable or non-verifiable in the field (falsifiability), and that the observation protocol (excavation, survey, etc.) must be fully described along with the ultimate conclusions so they can be assessed independently by others, then Jefferson did it all. His data recovery was in response to a European questionnaire that had at its heart an assumption (the question) that animals and humans removed from the Old World to the New would inevitably degenerate (becoming smaller and less complex) because of some presumed environmental deficit. Jefferson reasoned that Native American remains stratigraphically below others in burial mounds would be older than those above; hence (according to the questionnaire's assumptions) the artifacts in those lower strata should be more developed (and the makers physically larger). Dug stratigraphically and compared layer by layer, the material remains did not show any differences – Jefferson uses the new Enlightenment canon of sense perception, empirical knowledge derived from experience to falsify the initial "hypothesis."

The absence of a falsifiable hypothesis complicated the efforts recently to rehabilitate the reputation of Rocque Joaquin de Alcubierre, the Spanish military engineer in the employ of Charles of Bourbon, King of Naples, and to name him the Father of Classical Archaeology for his 1738 excavation of Herculaneum. Usually vilified as a plunderer and foe of his more systematic successor, Karl Weber (excavated from 1749), he is now acknowledged for at least making lists of the antiquities coming up from his shafts into the Vesuvian detritus and some note of where these treasures were found. As for his research question (or hypothesis) and his plan of attack (or protocol) – there were none of these. The same can be said for scores of other plunderers and curiosity seekers devastating the countless barrows, mounds, ruined cities and tells of Europe and, increasingly, the new territories of European expansion during the years of the Enlightenment.

Post-Enlightenment it is difficult to comprehend just how liberatingly radical (and recent, only with Locke's 1690 *Essay Concerning Human Understanding*) and dangerous to the established order was this experiment with how we comprehend the world from the material evidence around us. If, however, Jefferson can be called the sole "accidental" archaeologist of the Enlightenment, he was nonetheless attacking his problem in a quite current archaeological manner. By the Enlightenment period's close, the problem of comprehending the motivations of peoples distant in customs or in time was turned on its head compared to how pre-Enlightenment scholars would have proceeded: They may be us as we once were, but they are us, nonetheless.

Intellectual Liberation: The Enlightenment

Europe's world expansion would not have sufficed to challenge medieval ecclesiastical doctrine that all but the Christian chosen were lesser approximations of God's image. There was far too much need for justification of conquest and genocide, such as Fray Ginés de Sepúlveda's (c. 1560) assertion that the so-called savages of the Americas were not even human. All that began to change with the realization that the rude stones and bones being unearthed in increasing numbers from the ancestral soil of Europe looked undeniably like those made by so-called barbarous tribes far away. The best Enlightenment minds asked the archetypal archaeological question that rests the basis for all current assertions of universal human rights: Are they what we were once – or are now still? Beginning in the mid-seventeenth century, new inquiring minds of Europe began to invent a new authority to interpret distant savages and their own distant ancestors. The *philosophes* looked upon the face of modern savages and ancient brutes and saw there none of the revealed certainties of the senescent medieval order.

Intellectually, that medieval order, God's Order, was starting to crumble. The Enlightenment was not conceived in a vacuum: since the sixteenth century, curios from voyages of discovery and amateur diggings, together with natural science samples, found their way into

Wunderkammern or Cabinets of Curiosities. These were far more than proto-museums. They were the mirror of the universe, where Divine purpose was exposed to scrutiny of reason. Scholars scrutinized their *Wunderkammern* for universal, mechanical laws championed by Descarte, Kant, Buffon, and Newton. Dangerously, humans, too, were forged into God's Great Chain of Being and so belonged with all things measurable – animate and inanimate and present and ancient (as brilliantly presented in Arthur Lovejoy's *The Great Chain of Being*). Now, if God made the Great Chain, then He must have made it according to immutable principles. It was a given of the established order, that authoritarian cabal of clerics, princes and pre-Enlightenment scholars, that each link in the Great Chain was a unique, well-differentiated "natural species." Each link was present since the creation, each unchanging – each so different from its neighbors on the Chain that one could talk of an organic barrier to the understanding of the mental processes of one from the next just as unassailable as the genetic barrier between species. This was particularly the case in the matter of the "micro-" Great Chain of Being on which each people of the globe stood arrayed, a reflection in small of the "macro-" Great Chain of all organic life forged by God.

Linnaeus was ranking species, not just classifying them, when he invented, *Homo troglodytes*, the link to the great apes immediately below the rudest of living primitives. So too, as late as 1790, Soame Jenyns produced a seriation of humanity from the "brutal Hottentot" to Newton. However, as early as 1636, Peter Heylyn's *Microcosmos* makes a direct comparison of North American Aboriginals to Europeans 300 years after Noah's flood. While the members of the Scottish Enlightenment (Ferguson, Stewart, Adam Smith, Millar) and their French counterparts (Turgot, de Concorcet, Buffon, Montesquieu, Voltaire) were to make God an irrelevancy to the discovery of the principles of causation, they transformed how one uses the evidence of ancient times to know the workings of the minds of people very different than themselves. First, they championed the abandonment of the idea of a radical divide between the European and the rest of humanity. Secondly, there evolved an equation of ethnographic distance from Europe with the historical distance ancestors. This, in and of itself, was not particularly revolutionary. Certainly, it would not have been considered a remarkable insight when, in 1750, Turgot stated that all stages of development leading to the European nations were represented somewhere in the world. What was pioneering were the methods of analysis and the initial presumption of a transcendent, constant human nature.

If we take 1690 (publication of Locke's radical exposition of empiricism and the implicit challenge to the established order by denying the monopoly of a God-given warrant of Truth and Authority) as the beginning of the Enlightenment (and the 1789 beginning of the French Revolution as a somewhat arbitrary end), then what were the particular threads of thought in the multicolored weave of Enlightenment thought that made a modern archaeology possible?

Paired with the persistent anti-clericism of the period was a faith in science. Science, not in the sense of a protocol of skeptical testing and analysis that it has recently come popularly to mean, but as a liberation of the mind, of human consciousness from ignorance and immature (read: received) doctrine. Each an authority unto him or her self, each demanded by Locke to understand the world by the testimony of her or his own sense perceptions, each person had within the soul of a scientist and student of natural laws of the universe and of humanity. In the case of moral (human) laws, the goal of these studies was to isolate causation of human history by pragmatic observation, classification, and experiment. The laws thus revealed were to possess the same structure as natural science laws and, because they were lessons to reduce humanity's pain, were of even higher moral status. The means were open mindedness and unfettered empirical inquiry; the results would be democracy, equality, and progress! Laws were predictive. Infinite perfectibility was the law of nature. Societies develop along universal, linear stages, each developing out of the preceding. Scientific society was the highest moral end of history. As Kant wrote in his 1784

Was ist Aufklärung?, "Enlightenment is man's release from his self-inflicted immaturity. Immaturity here means man's inability to make use of his intelligence without direction from another."

History could only be treated as an equal to natural science because of an abiding faith that all humanity was borne of a common ancestor. This (monogenist) faith in global innate equality of intelligence, articulated by Buffon (1749) and Ferguson (1767), is passed on to the next generation by Prichard (1813, 1841) as the "psychic unity" of the social evolutionists. However, the idea of progress (that science, or a society directed by a committee of scientists, would inevitably lead to a higher quotient of happiness or lessening of pain, or of enlightenment in the world) was not so highly regarded by all *philosophes*. Rousseau, with his 1755 *Discourse on the Origins of Inequality*, challenged the abiding faith of luminaries, from Voltaire to Adam Smith, that (empirical) discovery of laws of human history would ineluctably lead to a better humanity. Rousseau's prescription was that the material gain that was science's harvest, especially private property and luxury, would lead to greater inequality, to the degeneration of society. Lost, perhaps, in most discussion of Rousseau is the shared assumption, his and his adversaries, that all humanity, all races, and all social classes partake of a universal psyche. By the mid-eighteenth century, at least in the rarified world of Enlightenment discourse, the revolutionary idea of a common human mind was unremarkable.

Eventually, the expression of this idea of a global innate equality of intelligence with greatest impact (albeit indirect) on archaeology was by the tragic Marquis de Condorcet, in his ten-stage, unilinear history *Esquisse d'un Tableau Historique des Progrès de l'Esprit Humain* (1793). This is the most revolutionary thesis of the Enlightenment in his use of antiquity to develop, empirically, not just a history of civilization but a "law" of the role of science in the grand schema of moral progress, justice, and human rights. Importantly, modern hunters and gatherers are survivals from the original human condition. They may still be steeped in ignorance because of environment or historical accident, but not because of biological (racial) barriers to progress or because they degenerated from an earlier condition. Stage by stage, the now familiar Enlightenment concepts of a comprehendible, universal, and law-driven humanity are expressed. Progress comes as ignorance is stripped away and as science increasingly drives rational society. Progress in the natural sciences will be followed by that of the moral or philosophical sciences, the latter with equal or more import for humanity. Expanding knowledge in all sciences leads inevitably to individual freedom and to more justice. And (as a methodology), study of the past reveals a causal order (laws, if you will) that can be rationally understood and that apply to all of humanity. Thus, the problem of comprehending the motivations of peoples distant in customs or in time was really a non-problem: They may be us as we once were, but they are us, nonetheless.

The third Enlightenment "Big Idea," no less foundational to archaeology than liberating science and global innate equality of intelligence, is one that rarely gets mention. Denis Diderot and Jean le Rond d'Alembert edited the Enlightenment's signature publication, the 28 volume *Encyclopédie* from 1751 to 1771. The spiritual importance to archaeology is in its full title, *Encyclopedia*, or *Analytical Dictionary of the Sciences, Arts, and Crafts*. Radical! In the last word of the title, *Crafts* or better in the French *Métier*, the once despised (or at least neglected) "mechanical" techniques and tools of everyday craftsmen were elevated to equal significance with the more cerebral sciences and (fine) arts. Hundreds of articles on the everyday craft of working with material things and hundreds of pages of engravings of tools, all for the purpose of showing how human experience and understand, are embedded in the mastery of mechanical things. If all that archaeologists can and have ever done is to read in the fragmentary material evidence the story of how peoples in the past acted upon the world as they perceived it, how better to try to comprehend the intentions and motivations of those peoples than through examination of the tools by which they acted upon the world? Ancient tools are not, of course, the be all and end all of archaeology. But arguably Diderot (himself the son of a master

cutler) sped us on the way from an exclusive celebration of fine arts (as in Johannes Winckelmann) to the omnivorous purview of archaeology today. (Junior archaeologists forced to create their first lithic or ceramic typology curse Diderot still!)

Reactions to the Enlightenment

The Enlightenment remained in its armchair. Real, systematic excavation as we recognize it today would have to wait until the late nineteenth century (with Pitt Rivers at Cranborne Chase (1887–1898) and as a profession, much later). More troubling as the nineteenth-century reaction against revolutionary ideas of universalism and Egalité and against the horrors of the French Revolution and the Napoleonic betrayal set in, speculation about the past fell increasingly into the hands of nationalists and mystical Romantics. There were Enlightenment-like carry-overs, to be sure. Saint-Simon (1813–1825) and, especially, August Comte greedily consumed classical antiquity and comparative prehistory as they carried the sputtering torch of progress and unity of method with the natural sciences. In his *Système de Politique Positive* (1824) and *Cours de Philosophie Positive* (1830–1842), Comte articulates a grand hierarchy of all the sciences. Social physics (history) will be the last to mature but will boast the profoundest laws. In the end, however, Comte's grandiose plans for history simply became irrelevant to the growing numbers of advocational field archaeologists. For them, the living prehistory represented by the diverse peoples of the new colonies overseas served as a quite adequate and uncomplicated illustration of how ancient peoples lived. The larger Enlightenment project of divining laws of moral progress by which all of humanity could be lifted up was largely abandoned. If those savages had had a history, it was irrelevant. The hand axes of Australian Aboriginals were just hand axes, with no innate lesson to teach about causation of history or about progress. These nationalists and mystics (e.g., Hegel. Herder, Schiller, and Fichte) held that each people had their own particularistic history, determined by geographical accident or race. Nationalism melded with the conceit that natural selection produced some races superior in intelligence and capacity for complex social institutions, while others – argued Lubbock in his *Prehistoric Times* (1865) – were destined only for cultural stasis.

Still, Enlightenment concepts lived on. Social evolutionists held as unremarkable the belief that variability in the ethnographic record mirrors humanity's past – so argued Lubbock in 1865. So Sollas still maintained in his 1911 *Ancient Hunters*, where he equates Tasmanians with the European Lower Paleolithic society, the Middle Paleolithic with Australian Aboriginals, and the Upper Paleolithic with the Eskimo and Kalahari San. The social evolutionists reinvented bastardized versions of "psychic unity": Within the same stage, ethnographic and archaeological peoples share the same emotions and same intellectual capacities. We see this in Sir James George Frazer's (1890, 1906–1915) belief in cross-cultural survivals of primitive totems and religion (eventually to give way to scientific thought).

One would be forgiven for seeing in more recent theoretical "stances" of archaeology (as anthropological archaeology) a pendulum swing toward and against fundamental Enlightenment contributions. We see a swing against in Boas' rejection of cross-cultural unilinearism and his and his immediate archaeologist students' writings against all forms of speculative, comparative laws of evolution, race, or progress. The field swings toward Enlightenment ideas with those optimisms of the new archaeology's first flush that archaeology becomes a science would transform the discipline into a true anthropology of the past. More recently, we have witnessed the post-processual recoil against renouncing all attempts to make archaeology into an anthropology aping the natural sciences. These theoretical swings and debates and even in the language in which those debates we see revealed the Enlightenment's deep legacy.

From mid-twentieth-century European and North American skepticism that the motivations of the long-dead could ever be known and W. W.

Taylor's argument that the archaeologist can never be a part of the past, so it is impossible for him or her to reconstruct a civilization, to Louis Binford's late career repudiation of an earlier position on the question of whether ancient beliefs and intentions could ever be reconstructed and then the post-processualists' astonishing reinvention of an empathetic source of real knowledge of the past (Hegel and Herder would have been proud) – the Enlightenment belief that the mind (intentions and motivations) of past peoples might be comprehended by the living is alive and well (and hotly debated).

At the end of the day, one of the enduring legacies of the Enlightenment (and of debates post-Enlightenment) is the general acceptance that archaeology is the study of the remains of past people's actions upon a world as socially constructed and perceived. Few archaeologists would go so far as to say that the process of social construction is mystical and, hence, utterly unknowable empirically. Behavior does not depend upon an inner logic (manual of translation) that is forever hidden from outsiders to the community. There is an emerging optimism that past motivations can be at least partially revealed through the investigation of how symbols and objects function as devices or insignia communicating peoples' view of themselves. That would be a novel way of putting the issue, one that would make the *philosophes* scratch their chins (scratch beneath their wigs?). But it is a concept that would not be completely alien.

Archaeology in Transylvania

Csaba Szabó
University of Lucian Blaga Sibiu, Sibiu, Romania

State of Knowledge and Current Debates

Although there is no such modern political entity as Transylvania (today part of Romania), the theoretical archaeological currents and practices used in this historical region since the beginning of the nineteenth century make it a well-defined entity in archaeological research. In the following, the notion of Transylvania is used to describe the part of Romania located inside the Carpathian Basin, including the regions once referred to as Partium and Banat, as historical-cultural regions.

From Antiquarianism to Modern Archaeology (1458–1859)

The history of antiquarianism in Transylvania has its roots in the medieval urbanization of the region when the prehistoric, Roman, and early-medieval monuments were looted and reused in the first monumentalized building projects of the Saxon and Hungarian cities (Szabó 2014). During the age of János Hunyadi and Mathias Corvinus (1458–1490), the first collections of Roman monuments were established at the royal court of Mathias Corvinus, followed by numerous Renaissance collections of bishops and the high elite of the local aristocracy (Balogh 1943). The first documented excavations and archaeological discoveries were made in the eighteenth century when the Habsburg administration changed the urban landscape of the medieval towns radically. Due to the large construction sites, such as the Vauban forts of Alba Iulia or the military

buildings in Cluj and several other towns in Transylvania, many of the Roman and medieval sites were severely damaged. The territorial expansion of the urban areas and the agricultural reforms of the eighteenth and nineteenth centuries accelerated the increase in the number of excavations. Important discoveries were made in this period, for instance, at Várhely, the Roman Colonia Sarmizegetusa, Alba Iulia, the Roman Apulum (Szabó 2013), Szilágysomlyó (Stark 2000), and Nagyszentmiklós (Bálint 2004). Numerous Roman and prehistoric sites were discovered at the end of the eighteenth century. Some of them – such as the Roman baths of Herkulesfürdő (today Băile Herculane) and the wax tablets of Verespatak (Alburnus Maior) – were discussed widely in European academia. The capital of the Dacian Kingdom, Sarmizegetusa Regia, was discovered in 1804 also by the Habsburgic administrative and military staff of the region. Antiquarianism changed during that time from a privilege of royal and clerical (aristocratic) activity into a widespread fashion of scholars, travellers, and treasure hunters (Bărbulescu 2012). Important studies on the archaeological heritage and visible ruins of Transylvania were written in the first decades of the nineteenth century. First systematic excavations were conducted by Károly Torma at various sites of the Roman Limes. Due to the political status of Transylvania as part of the Habsburg Empire, most of the remarkable finds were transported to Vienna from the eighteenth century till 1867. Likewise at the end of the eighteenth century, the first systematic collections of antiquities emerged, e.g., the private museum of Count Batthyány Igánc from Karlsburg (Alba Iulia, Gyulafehérvár) and Samuel Brukenthal from Hermannstadt (Sibiu, Nagyszeben).

As a result of the Enlightenment and the so-called Hungarian Reform Period, the elite of Transylvania began to embrace the idea of collecting, promoting, and protecting the cultural and archaeological heritage of Transylvania; however nationalism plays a minor role in this period, which will be more powerful after 1867. As a result of this almost 50-year-long process, in 1859, Imre Mikó founded the Transylvanian Museum Society. This institute – formed and organized after the model of the Hungarian Academy founded in 1825 and the Hungarian National Museum in 1802 – was meant to be the supreme academic forum for scholars in this region. With the foundation of the Transylvanian Museum Society, the period of private collectors and sporadic excavations slowly ended, and a period of systematization and organized heritage protection began.

Transylvanian Archaeology in the Belle Époque (1859–1918)

The second half of the nineteenth century is marked by several political and legal changes. After 1867, when the Austro-Hungarian Empire was established, Transylvania became a part of the Hungarian academic environment again. This meant also a legal shift in the protection of the archaeological heritage. As a consequence of the foundation of the Transylvanian Museum Society in Cluj (Kolozsvár), in the 1870s and 1880s, numerous local museums and institutions were established. Their role was to enter in the systematic network of museums from the Hungarian Kingdom, organized and monopolized by Budapest and the National Inspectorate of Museums (Szabó 2016: 152–154). Archaeological excavations in urban and rural environments were organized by scholars (usually teachers financed by local politicians) from these local associations from Fehér (Alba), Hunyad (Hunedoara), Szilágy (Sălaj), Temes (Timiș), and several other counties (Szabó 2016: 154–160). Their impact was enormous, and it still defines the museum-related and archaeological heritage policies of this region.

The associations and some of the leading personalities of this period played an important role in the foundation of several museums; they also edited and published the first comprehensive monographs on the history and archaeology of Transylvania and promoted the protection of archaeological heritage for the greater public. The systematic excavations carried out especially by Gábor Téglás and his team in Colonia Sarmizegetusa (Boda 2014), by Zsófia Torma in Tordos (Coltofean 2014), and by Béla Cserni, the "father" of urban archaeology in Transylvania, in Alba Iulia (Szabó 2016), represent not only important contributions to local archaeological heritage research and preservation, but they also

introduced new methods to the archaeological process such as photography, site journals, highly accurate reports, documentation, and multilingual publications. Cserni was a pioneer not only in urban and rescue excavations but also in public archaeology. His work is essential to understand the topography and history of numerous sites in the region even today. The first department of archaeology in this region was founded at the new university of Kolozsvár (Cluj) at the end of the nineteenth century. The strong personality of Béla Pósta (Vincze 2014) created an archaeological school, which dominated all the excavations and the actions in the protection of archaeological heritage in Transylvania and Hungary between 1899 and 1916. His most important contribution to the field was the systematization of museology and university education of archaeology, which became an official discipline in Transylvanian research and higher education after 1874. His was also the very first attempt to create a real "Transylvanian" school of archaeology within the Austro-Hungarian academic environment, which communicated with the center (Budapest) and the international community but focused on local particularities and problems.

The downside to his school and dominant personality was the monopolization and centralization of the archaeological heritage and the excavations, which marginalized local museums and scholars. This period marks also a change in the archaeological narratives in Hungarian historiography. While publications from the early nineteenth century were much less ideologically influenced, publications from the end of the century are part of the larger European trend of nationalistic tendencies in archaeological thought (Diaz-Andreu 2007; Anghelinu 2014). While till the mid-nineteenth century, Roman and prehistoric archaeology was favored, after 1867 and especially after 1896 (i.e., the year of the Hungarian millennial celebration), early-medieval and Hungarian archaeology was emphasized. This tendency also reflects the imperialistic ideology of contemporary Hungarian academia and research. The relationship between Budapest and Kolozsvár (Cluj) reflected the same, central-periphery relationship as it was attested between Kolozsvár and the provincial museums of Transylvania (Szabó 2016). While some of the regionally important finds were transported to Sibiu and later Cluj, the most remarkable objects were sent to Budapest. Most of them are still in museums in these locales.

Parallel Discussions: Archaeology in Transylvania in the Interwar Period (1918–1939)

After 1918, Transylvania became part of the Romanian Kingdom. Beside the political changes, the archaeological narratives suffered also an ideological shift of paradigms in numerous fields. The Hungarian academic environment – which had dominated the local research until that point – was marginalized or left the country, being replaced on the institutional and educational level by a new Romanian group of scholars (Anghelinu 2014: 113–134). This affected not only the archaeological narratives but also the administration and infrastructure of the historical and archaeological monuments. Although a Commission of Historical Monuments for Transylvania was established, the looting of the archaeological heritage in the 1920s and 1930s increased significantly, especially in urban environments (for Alba Iulia as case study, see Szabó 2014). The number of systematic and rescue excavations decreased significantly. Both theoretical discussions and archaeological research came to emphasize Dacian history and the continuity of Latinized populations in Transylvania after 271 A.D. Most of the sites chosen for excavations and for preservation by the Commission and the leading archaeologists were related to Dacian history (Grădiștea Muncelui/Sarmizegetusa Regia) and the Roman period (Colonia Sarmizegetusa). Transylvanian archaeology as such ended and became integrated into the leading archaeological schools from Bucuresti. The most emblematic figure of this period was Vasile Pârvan, often referred to as the father of modern Romanian archaeology. His school from Bucuresti was influential also in Transylvania, dominating the major research policy of the new Romanian academic elite from Cluj. However, the charismatic personality of Constantin Daicoviciu created a new school of ancient studies and archaeology in Cluj in the 1930s which was to dominate the field till the

mid-twentieth century and creates a certain provincialization of the Romanian archaeology. His influence marked not only the higher education in history and archaeology, but as the president of the Commission of Historical Monuments, he also decided the major currents in field archaeology. His publications on the ancient history of Transylvania provoked a severe reaction from Hungarian academia, creating a long-lasting debate on continuity and the ethnogenesis of the Romanians (Visy 2015).

From Marx to Ceaușescu: Archaeology During the Communist Regime (1945–1989)

Although the political ideology of Great Romania and the dominance of Bucuresti in local archaeological narratives were observable in the 1930s, the so-called Transylvanian archaeological school retained a certain autonomy until 1945. The rise of the communist regime, however, imposed a much stronger and centralized ideology in classical education and field archaeology (Matei-Popescu 2007; Anghelinu 2014: 155–239). In the 1950s, Marxist ideology influenced the archaeological narratives on the ethnogenesis of Romanians. Instead of emphasizing the "imperialist" and Western (Roman and Latin) origins of the Romanians, new studies were focusing on the Slavonic elements and the history of Romanians. Excavations at early Slavonic sites in Transylvania played a crucial role in the creation of these new narratives (Horedt 1958). Transylvanian archaeology in this period played a crucial role in the establishment of a strong Marxist, united country. In the emerging narrative, the history and materiality of this region was used to legitimize the new political regime. Roman sites and history were ignored or played a less important role till the 1960s when another shift in ideology occurred. With the rise of Ceausescu in 1968, Romanian archaeological narratives started to combine nationalism with Marxism. Dacian and Roman history were used to legitimize the personal cult of the new dictator. Excavations in the Orastiei Mountains and other Dacian forts in Transylvania were in focus again, as were the Dacian ethnical elements in the ethnogenesis discussions. Constantin Daicoviciu, as the leading scholar of antiquity and archaeology in Cluj, changed his political affiliation several times to save the position of Cluj as the center of ancient studies. This effort created a conflict with the political elite from Bucuresti and marked his carrier and, indirectly, his personal life too.

Due to the large urbanization projects of N. Ceausescu in the 1970s, urban archaeology gained unprecedented dimensions in Alba Iulia, Cluj-Napoca, Drobeta-Turnu Severin, Turda, and other cities. Large reconstruction projects were initiated at various Roman sites, favoring especially the military archaeology and the *Limesforschung* in Romania (Gudea 1997). Transylvanian archaeologists and classicists, such as Constantin Daicoviciu, Hadrian Daicoviciu, Ioan Glodariu, Nicolae Gudea, and Ioan Piso, ensured the position of Cluj as leading archaeological school of the region, while others, such as Ion Berciu or Doina Benea, established regional centers of archaeological investigations in Alba Iulia and Timisoara. Some of these charismatic personalities (especially Hadrian Daicoviciu) became celebrities of their time. Hungarian archaeologists and the once well-known Béla Pósta School became less and less important in the formation and maintenance of a specific Transylvanian archaeological narrative. Gyula László and István Ferenczi as archaeologists and András Bodor as the only Hungarian classicist in Transylvania created a bridge between the new school of Daicoviciu and the old, Béla Pósta period.

A more obvious clash and academic debate existed between Hungarian archaeological narratives from Hungary on ethnogenesis and early-medieval archaeology and the Romanian one. The publication of a new Hungarian companion on the history of Transylvania (Köpeczi 1986) had a scandalous impact on the narratives of the Ceausescu regime.

A particularity of this period is the slow internationalization of Romanian archaeology. Although the mobility of the scholars in this period was extremely limited, some of them were able to participate in international conferences at least in the 1970s. Romania also signed almost all international cartas and agreements on the protection of archaeological heritage and patrimony rectified in this time. Few foreign

Archaeology in Transylvania, Fig. 1 Transylvania in 1910. (Source: *Nemzeti Internetfigyelő*)

exhibitions on the famous Roman and Dacian treasures and the archaeological heritage of Romania were presented outside the country (Condurachi 1963; Condurachi and Daicoviciu 1972). Numerous local museums were newly established and organized after the ideology of Ceausescu. Most of these interiors still exist, as a historical memento for Communist narratives of archaeology.

New Tendencies and Perspectives in Archaeology and the Case of Transylvania (1989–2016)

Since the fall of the Communist regime, archaeological narratives and practices have changed numerous times in Romania. Archaeological legislation suffered many changes over the last quarter of a century (Borș 2014). Although Romania became a member of the European Union and rectified most of the international treaties, the increased number of rescue and urban excavations is rarely documented or published properly. International projects and collaborations create new possibilities to attest, document, and present the archaeological heritage of the country, although modern museology and interactive methods still need to be improved. Archaeological databases and online catalogues were already established in the last decade, although the national register of archaeological sites is far from being satisfactory or complete. The number of centers of archaeological education increased significantly, deconstructing

the Cluj-Bucuresti dichotomy, although the dominance of these two schools and their archaeological institutes are still attestable in publications and field archaeology too. Transylvanian archaeology as such at present is experiencing a revival as well. The heritage and the school of Béla Pósta were newly established in Cluj by the Béla Pósta Association and the Transylvanian Museum Society, who for many years has been organizing annual archaeological conferences and also created a by now well-established archaeological school for Hungarian students focusing mostly on local sites. Important schools and excavations were organized emphasizing the medieval history of Transylvania and establishing a first generation of medieval archaeologists in the region.

The Archaeological Institute and the National History Museum of Transylvania from Cluj represent also an important factor in the overall evolution of Romanian archaeology. The most visited archaeological museum of the country is still in Transylvania, Alba Iulia, while most of the publications and rescue excavations and major international projects are focusing on this region. From the 16,000 archaeological sites registered in Romania, 6000 are from Transylvania. In the last decade, collaboration between Cluj and Bucuresti has become much friendlier and ideologically less charged which many of the recently established committees and national commissions being formed by mixed groups from Transylvania and beyond (Fig. 1).

Archaeology of Affection

José Roberto Pellini
Departamento de Antropologia e Arqueologia, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil

Introduction: Butterflies in My Stomach

Two years ago, I was surfing the internet when I was struck by news that made me shake from head to toe. The Brazilian Federal Senate had just accepted the request to initiate the impeachment case against President-elect Dilma Roussef. A coup d'etat was beginning to unfold in Brazil. For a few seconds, I was unsure about what to say, how to feel, or what to think. I felt like I had butterflies in my stomach. I had the impression that, as I was reading the news, light fled, emptying the space around me. The atmosphere became heavy, dark, and very dense. Another feeling that was hard to explain. A set of intensities which I also found difficult to express and put into words. An overall feeling of discouragement washed over me. Over the next few days I tried to rationalize these feelings, to think positive, but this was not an easy task. These intensities seemed to haunt me. The problem was that everyone around me seemed equally drowned in this hopelessness. Obviously, those who supported the coup d'etat against President Dilma were visibly pleased, but the rest of people, over 70% of the population, were feeling just like me. I do not know if it was the uncertainty, the fear, or the anguish about an uncertain future that generated these sensations. All I can say is that I myself could not express what I was feeling. Everything was blue.

But what are these intensities that sometimes take over our body and that we struggle to put into words? What are these visceral intensities that sometimes invite us to activity and other times prevent us from even moving? Some would call them affections or affect, others would say they are emotions. What is the difference between emotion and affect? Is there a difference at all?

Far from being a new issue, such questions as these have been among the focal points of the so-called affective turn. Influenced by feminist thinking, queer theories, and the work of philosophers such as Deleuze, Spinoza, and Bergson, the affective turn emerged in the 1990s. The affective turn sprang up as an alternative that might overcome the dichotomies and dualisms of constructivism and theories of representation, especially those involving mind and body, action and emotion, human and nonhuman. However, the first problem we encounter when approaching the literature about affect is that there is no consensus about what affect is or what it actually means to affect and be affected. While some researchers use affect as a synonym for emotion, others prefer to differentiate between emotion, affect, feelings, and sensations. Among the latter, emotion is conceived in close association with judgment processes, while affect is conceptualized as an unconscious and bodily intensity. Emotion would be a socially constructed and culturally variable element whereas affect would be an asocial phenomenon. Therefore, while norms, values, and social structures determine both the emergence of emotions and their appreciation (Von Scheve 2016), affect is not subject to influences of an ideological character.

Re-reading of Deleuze's works, Brian Massumi – considered one of today's most influential proponents of the affective turn – has attempted to organize the differences between affection and emotion, feeling and sensations to put forth that feelings are personal and biographical phenomena, that is, that they are intensities originating from our life experiences as individuals. It is only when these intensities are socially categorized that they become emotions. Emotion would thus be the social representation of a feeling, the linguistic extroversion of a felt intensity. Affection, on the other hand, would be a pre-cognitive and pre-linguistic intensity which prepares our body for an action in a certain situation, i.e., it is a body's capacity to affect and be affected by something.

Background: Four Great Traditions

Thrift (2007) lists four major currents of thought about affection. The first theoretical approach is linked to phenomenology, mainly to the work of Sarah Ahmed. The second trend is associated to psychology, neuroscience, and the works of Sylvian Tomkins and Eve Sedgewick. A third line of thought would be associated with neo-Darwinian thinkers. Finally, the fourth way of envisioning affect is associated with the works of such philosophers as Gilles Deleuze and Baruch Spinoza. These different currents of thought are not exclusive or closed but intertwine and share some theoretical tenets, concepts, and structures of analysis. As a result, a deep and healthy theoretical diversity emerges with the benefit of encouraging a constant actualization on the part of these different approaches. At the same time, such diversity can become problematic when it is perceived as an overall incongruous use of concepts.

Among those theorists of affect associated with phenomenological thought, affect is conceived as a group of bodily practices that produce defined and visible gestures and a specific bodily conduct. To proponents of this approach, being affected by something is to evaluate and judge that something. In Ahmed's view, for example, before we are affected by something or someone, this something or someone must have a place that determines whether we will be affected in one way or another. Such a place involves psychic and social dispositions and dimensions, which means that this place is always in transformation (2004). For Ahmed, emotions are not just feelings that someone or something has, but feelings that cause bodies to open up to each other. According to Ahmed, "It is not just collective bodies that are shaped by emotion, it is through experiences like pain that we come to understand the surfaces of our own bodies, to understand where they collide with objects and others to set ourselves apart" (2004, 26). In this way even the most solitary of emotions is social. In Ahmed's view, since emotions are relational elements, we should not ask ourselves what emotions are but what they do.

Critics of phenomenological positions have pointed out that, whether or not they are grounded in affective theory phenomenological approaches rely on the idea of empathy, that is, that as humans we may experience things in similar ways (Harris and Sørensen 2010). This idea is directly grounded in the notion that sensations are universal and trans-historical. At the same time, in phenomenology, intentions remain trapped in repetition preventing the emergence of the new. According to Massumi (2002), phenomenology envisions the personal as prefigured or pre-reflected in the world, in a closed circle of intentionality. The act of perception or cognition is a reflection of what is already pre-embodied in the world, in an endless repetition of the same structures.

The second theoretical approach within affect studies is rooted in psychoanalysis and the Freudian conception of drive, that is, those psycho-physiological processes that are the basis for the development of human identity and motivation. Among the best-known drives are sexuality, libido, and desire. Within this framework, emotions are both manifestations and consequences of a drive. An early proponent of this approach, Tomkins (1962–63) considered affection an inherently psycho-physiological process and argued for the separation of drive systems from affective systems. Tomkins considered the drive system to be very restrictive, directed to specific objects, and temporally limited. In contrast, he suggested that such affects as anger, pleasure, sadness, happiness, etc. are more open, less directed to specific objects, and more temporally flexible. Tomkins proposed that affects could be bound up with things, people, ideas, sensations, relationships, activities, ambitions, institutions, and anything else, including other affects. At the same time, Tomkins advocated the existence of what he called "basic affective programs," that is, a stable evolutionary set of eight orchestrated responses that evolved to signal urgency and allow action to be initiated (Tomkins and Mccarter 1964, 120). The framework is called the paradigm of basic emotions and posits that basic emotions – also called affective programs – do not involve any

kind of cognition or belief about the objects in the world, since emotions constitute a fast, automatic, and evolutionary response meant to guarantee an organism's survival. The speed at which the affective system operates prevents affections from being appreciated by the cognitive system, thus creating a kind of lagging between both systems. In this sense, affects would be unintentional body responses operating below the threshold of cognition. Leys has thus shown that (2011, 440), "as Tomkins has put it, there is a gap or radical dichotomy between the real causes of affect and the individual's own interpretation of these causes. The result of Tomkins's approach is to suggest that affects are only contingently related to objects in the world."

Tomkins' work paved the way for cultural studies on affect, especially those that view affect as a phenomenon closer to feeling and emotion, and hence to human bodies (Thrift 2007, 34). For example, Eve Sedgwick's work *Touching Feeling* re-reads Tomkins' works from a feminist and queer standpoint, and turns to questions of affect and the topic of affectivity in search of new critical vocabulary for investigating and conceptualizing the subject of feminism as embodied, located, worldly, contextualized, and relational (Liljestrom 2016). *Among those thinkers who follow this current, less attention is granted to the categorization of affection as a general and universal phenomenon, and more emphasis is given to the relations between the body and the social.*

The third definition of affect is based on Darwinian thought, being largely associated with the basic emotions paradigm. For Darwin, emotions were universal and evolutionary processes which were not exclusive to humans. Darwinists argue that at all cultures share at least five emotions: anger, fear, sadness, disgust, and pleasure, and that each one of these emotions manifests itself in ordinary facial expressions. These expressions would be the result of internal physiological changes and not of linguistic or communicative processes. In this way for the Darwinists culture has little influence on innate emotions.

Finally, the fourth definition of affection is inspired by the works of such philosophers as Baruch Spinoza, Henri Bergson, Alfred North Whitehead, Gilles Deleuze, and Fellix Guattari and conceives affect as the ability of bodies to affect and be affected. For Spinoza, for example, affect is nothing more than an increase or decrease in one's ability to affect and be affected by another body. An increase in affective capacity causes positive affect and a decrease in this capacity causes negative affect. According to Spinoza affect is a relational process, where bodies present in a relationship are understood not as stable entities, but from their relational effectiveness (Slaby 2016). Extending Spinoza's concept of affect, Deleuze explains that affect is the movement from one state to another in the affected body and affection is the bodily trait, the state of the affected body (Deleuze 1987).

Starting from these ideas, Massumi (2002) defines affect as a visceral impact on the body, an incomprehensible sensory event that escapes intellection. When this event is actualized, it turns into emotion. Within this paradigm, affection is defined as an autonomous force between bodies that best expresses itself not in terms of emotions or experiences, but of intensities that increase or decrease a body's potential for action. Affect, therefore, refers primarily to the reciprocal capacities of bodies to affect and be affected (Clough 2008, 2). The bodies referred to here are not just human, but include all kinds of bodies that can affect and be affected, such as an animal's, a table's, a book, or a tree's (Von Scheve 2016). Affection is not a characteristic that pertains to an individual body but is a quality of the different kinds of relationships through which interrelated bodies are constituted, actualized, and constantly transformed. As Shabbar (2016) shows us, for Deleuze, an affective event is a meeting between the virtual and the real, a meeting of incorporeal concepts with the world's materiality. Virtual duration is, in Deleuze's most basic definition, real duration, but it is not tangible, whereas the real is what has been actualized from the virtual to form a subject or an object. Memory, for example, operates in the virtual. Whenever someone remembers something and transforms the mnemonic narrative into a story, a book, or a painting,

their recollections are updated and become an object (Shabbar 2016).

To think affection as a relational process, unconscious and pre-linguistic, forces us to think of agency as the efficacy that is distributed between human and nonhuman assemblages, and not as an intentional action. According to the authors: "As such, the assemblage is the engine of all social production – whether of bodies, subjectivities, thoughts, feelings, social forms and institutions, or political and economic orders" (Deleuze and Guattari 1983, 7). Consider for example the archaeologist-and-archaeological-site assemblage. At first glance this set would be formed by two entities, the archaeologist on one side and the archaeological site on the other. But both the archaeologist and the archaeological site only exist within this relation archaeologist-archaeological site. At the same time the archaeologist and the site are already assemblages of themselves. The archaeologist is an assemblage of bones, organs, veins, bacteria, memories, experiences, training, in the same way as the archaeological site is an assemblage including layers of sediment, vegetation, atmospheres, architectural structures, and the narratives that arise from it. Thus, the archaeologist-archaeological site assemblage includes all the archaeologist's knowledge, their friends, relatives, the educational policies that allowed them to graduate, the people responsible for these policies, the financial conditions that allowed them to research, the patrimonial policies that determine what constitutes an archaeological site, the communities involved in the evaluation of the place as an archaeological site, local cultural policies, communities, etc. The assemblage will also include past experiences, stories of the relationship between the archaeologist and the archaeological site, social norms, models of what it means to be an archaeologist, what an archaeological site is supposed to look like, how people should behave, and so on. The way in which all these elements affect each other will determine the type of assemblage that will arise – whether it is an academic, a community, a tourist, a mystical, a religious, or a power assemblage.

Imagine this archaeologist-archaeological site assemblage in a specific situation. For example, let us imagine that our archaeologist discovers their institution has cut research funding just as they are about to go on the field. The lack of money can generate anxieties and uncertainties, which will in turn affect their ability to act. Suppose they seek other sources of funding. In this process a new subjectivity arises, that of the entrepreneurial researcher. The archaeologist will have to go to meetings to meet new sponsors and thus devote more time to bureaucracy than to research, which in turn can generate frustration. Frustration can once again influence how they act and relate to funding institutions. At a meeting to get money, affectionate or angry behavior will affect the other party, possibly determining whether or not they will finally manage to get the financial resources. In this process, several other subjectivities are created, that of the entrepreneur, the manager, the technician who analyzes the contract, the bank that releases the money. When they finally get the money for the fieldwork, our – by then happy – archaeologist will gather his/her team, who will in turn also be happy and excited at the opportunity to embark on the fieldwork and conduct their own research. Such joys can generate the desire to buy new equipment, new technologies, to develop new field methodologies, etc. But at the same time, the archaeologist and their team will have to meet the needs, schedules, desires, and policies of the funding agencies, which might generate new anxieties and frustrations, triggering new and endless affective flows. These will also affect the archaeological site, which will be actualized in the form of an archaeological site, tourist space, or anything else depending on the affective flows present in these relations. All these interrelated affects, which generate new and endless affects, have practical effects on the assemblage. Affects will enable the body to feel emotions like love, sadness, envy, or desire. All these capacities are themselves affects representing the body's potential to act. Emotions are affects within the assemblage, they can alter, increase, or reduce the ability to act, they can amplify desires or not, influencing the ability of these bodies to generate

other affects and affect other relationships within the assemblage, contributing to the flow of affection (Fox 2015). Archaeologists become archaeologists not only through their training and specific knowledge but because they affect and are affected by students, archaeological sites, heritage laws, the materialities they study, etc. In the same way a place becomes an archaeological site through its relationship with archaeologists, with research institutions, with preservation laws, with local communities, with specific narratives and discourses, etc. In this way, all the affections present in the relation archaeologist-archaeological site are essential for the subjectivation and the formation of the different identities involved in the relation. These affections constitute concrete bonds as well as relational positions, based on a series of elements that together make up an assemblage (Von Scheve 2016).

Since affects produce capabilities in the assemblage, these capabilities will result in single or multiple attachments that will create new affects, generating an affective flow in the assemblage. Thus, watching a film about injustice can generate anger, desire for social changes, or the desire to donate money to a campaign, which in turn generates the image of a donor, thus producing other affections ad infinitum (Fox 2015). At the same time, discourses, narratives, statements, etc. are formed from the assembly, because as Deleuze and Gattari teach, each assembly is "simultaneously and inseparably a mechanical assembly and an assembly of enunciation" (Deleuze and Guattari 1983, 555).

Assemblages comprise the human and non-human relationships that occur as a consequence of the affective flows between parts of a relationship. Territorialization and de-territorialization also emerge from these flows. While some flows may aggregate, territorializing bodies and assemblages into relatively stable forms, other affective flows may de-territorialize the elements of an assemblage generating new and unique capabilities that resist this territorialization and disassemble the assemblage. Clough (2008, 15) calls this whole process an economy of affect. According to this author, affective capacities sew bodies in terms of attention, arousal, interest, stimulation, action, reaction, and inaction. Here, assemblages of bodies, subjectivities, and experiences flow together with social movements, organizations, political doctrines, and geo-economy.

Debate and Critics. Life Is Not a Bed of Roses

As has been presented so far, affect seems to rely on at least two major theoretical references. On the one hand, it is used to denote a force or intensity of relationships or something that circulates between different types of bodies. On the other hand, it denotes modes or states of the human body and the feelings and capacities that accompany those modes (2011). In both cases affection is thought of as relational, that is, it is not limited to individual bodies but is part of the intensities of relations or resonances between bodies.

Another shared characteristic of both approaches is the idea that affection is independent of meaning and cognition. Much of the idea of unintentionality is anchored in an alleged separation between the affective system and the cognitive system. For Leys (2011), both cultural theorists and neuroscientists see affect as a question of autonomous responses occurring below the threshold of consciousness and cognition. This proposal arises from the idea that there is a time lag between the decision to act and the action itself.

Massumi (2002) makes use of a well-known experiment on consciousness and the body to substantiate his proposition that affection is pre-cognitive. The experiment concerns the relationship between conscious intention and brain activity conducted by Benjamin Libet in the 1970s. In the experiment briefly described by Massumi, people with their hands on a table were invited to flex a finger and inform when they were aware of their decision or intention to perform this movement by observing the spatial position of a rotating point in a large clock that measures the fractions of a second. Libet found that the actual

finger flexions occurred 0.2 s after the subject recorded his decision. But the apparatus used to monitor brain activity recorded a significant activity 0.3 s before the subject could record their awareness of his decision. In other words, there seemed to be a half-second delay between the beginning of the body-brain event and its completion in the form of finger movement. Libet concluded that unconscious brain processes initiate actions before conscious intent appears. So according to him the brain deceives us in creating the illusion that we consciously decide matters and that our actions are personal events.

Gallagher (2006) criticizes Libet's work showing that it is only when the normal mechanisms of motor system control fail that people are placed in the experimental position of Libet. Based on phenomenology, the author puts forth a distinction between intentional, usually but not always conscious, and motor movements, which are generally unconscious, suggesting that Libet's experiments apply not to intentional actions but to motor movements, whose control we normally expect to be unconscious.

In the end, as Leys points out (2011), the problem is not the idea that many bodily processes occur below the threshold of consciousness. The problem concerns the implications that Massumi seems to derive from this idea, which, Leys proposes, led Massumi to accept the idea that the mind is pure consciousness. According to Leys, Massumi entertains the false dichotomy between mind and matter by reinforcing the idea that in order for something to be fully conscious the only alternative is to regard it as corporeal or material. In this view, affects would be a set of innate behaviors and expressions of a brain and body that are triggered automatically and that operate out of the domain of consciousness and intentional action.

Affect, Discourses, and Relationality

In attempting to overcome the problems of unintentionality involved in the Theory of Affect, Lisa Blackmam, Joonas Lahtinen, Anne Rutherford, Andie Shabbar, Jessica Ringrose, Emma Renold, José Roberto Pellini, and others have attempted to ground a discussion of the idea of affect on Karen Barad's posthumanist theory and her concept of intra-action. According to Barad (2007), all phenomena, including affect, discourse, and felt experience, are always involved in processes of intra-action. The concept of intra-action "signifies the mutual constitution of entangled agencies. That is, in contrast to the usual 'interaction,' which assumes that there are separate individual agencies that precede their interaction, the notion of intra-action recognizes that distinct agencies do not precede their interaction, but rather emerge through their intra-action" (Barad 2007, 33).

Taking this idea as a starting point, Lahtinen (2015) proposes that human perception is an intra-action process, where sensory effects are automatically brought into language and transformed into the experiences of a self-conscious "self," inevitably rendering human perception both material and discursive. This means that whenever we perceive something, we are immediately signifying this something, so perception is the simultaneously action of feeling intensities and of signifying them. According to Slaby (2016), what determines whether a perceptual-affective process is an instance of fear, sadness, anger, or some other type of sensation is the general pattern in which these feelings are systematically articulated (Ahmed 2004). To Slaby (2016), whether my negative feeling about something constitutes fear will depend on that particular feeling's relative position within a systematically extended pattern of properly related assessments. None of these elements has priority over others; they operate through intra-actions, where each element constitutionally depends on the others. This understanding of material-discursive practice determines that agency is not a product of human will, intentionality or subjectivity, but the result of an ongoing process of becoming. Discursive practices and material phenomena are not established in an external relation to one another, since the material and the discursive are mutually involved in the dynamics of an in-action. Thus, the relation between the material and the discursive is one of mutual entanglement. Neither discourse nor matter are ontologically preexisting and prior to the relation. If for Deleuze (1987),

the virtual and the real are mutually exclusive elements, for Barad (2012) there are no mutually exclusive aspects to matter.

The idea that discourses and affections are mutually constituted from intra-actions can be exemplified by the concept of distribution of the sensible proposed by Jacques Rancière (2004). This author uses the phrase "the distribution of the sensible" to refer to the implicit laws regulating the sensible order, a self-evident perceptual system based on the modalities of what is visible, audible, and sensible, as well as what can be said, thought, or done. The distribution of the sensible includes both forms of inclusion and the exclusion of the sensible. The sensible does not refer to any kind of judgment but to that which can be apprehended by the senses. Bodies constantly record information from the world through their perceptual systems and therefore constantly change their affective mode through processes of intra-action. Most of the time this happens subtly, with many changes taking place without the subject being aware. However, depending on intensity, context, or relational position, we can become aware of these changes and ascribe certain causes to them. Affect has effects mainly insofar as it alters the body's ability to act. This can happen in many ways, through changes in cognitive and perceptual processing, changes in the endocrine and hormonal system, or changes in the autonomic or peripheral nervous system (Von Scheve 2016).

Archaeology and Affect

Affection is still a relatively new subject in archaeology, mainly because archaeologists think of affect and emotion as topics which are too abstract to be approached scientifically.

To Hamilakis (2017), for example, affect is a productive force that articulates different elements in an assembly. The author points out that this productive force is necessarily set in motion through sensoriality, which he perceives as incarnate action. For Hamilakis, affection cannot be separated from the senses or the sensory, since the role he ascribes to the senses is not to allow the organic body to operate but to allow affectivity to establish affective connections with other bodies.

Pellini (2018), along the same lines, argues that affection, senses, memories, and narratives are all formed relationally through processes of intra-actions. For this author, affection cannot be thought of as prior to the process of signification, since feeling and meaning are part of the same relation that arises through the intra-action of different elements. In this approach, affection does not pertain exclusively to humans, since the very constitution of the human is defined by the agentic cuts within an intra-active relationship (Barad 2012).

Harris and Sorensen (2010) have proposed a complementarity between affection and emotion. They have therefore developed a vocabulary that attempts to provide a parameter of analysis for past affects and emotions. The author suggests working with the terms: emotion, affective fields, attunement, and atmosphere. Emotion is the incarnate act of being affected and affecting, of moving and being moved; affective fields are networks of people and things through which emotions are generated; attunement is the practice of meeting the material world and its emotional qualities; and atmosphere is the emotional experience engendered by being in a certain place and situation.

The Future: Affecting and Being Affected?

There is still no consensus as to what affect is, whether it is a noncognitive intensity, a culturally determined emotion, an evolutionary or a social and phenomenological force. Neither is there a unanimous position about whether it is intentional or not, whether it is social or asocial. However, there is no denying that discussions about affect have opened up avenues of research within the human sciences, especially those focused on understanding the body, agency, relationality, post-humanism, and post-phenomenology.

While it remains unexplored in archaeology, affect has a great potential to change the discipline, especially when considered from the point of view of relationality. Understanding how

affect, senses, memory, narratives, body, and the social intertwine is fundamental to understanding both the past and the present. The idea of affect shows us that it is impossible to conceive body and mind, passion and reason, as separate phenomena. To think of affection is to think not of what a thing is, but of what it can do, of how different entities are captured within a relationship.

To think of affection is to think of politics, since power and control, cannot be understood as a production of the subject, as an expression or representation of norms, but as a "never-ending modulation of moods, capacities, affects and potentialities, assembled ... in bodies of data and information" (Clough 2008, 19). As Thrift (2007) reminds us, affection has always been a key element of politics and the subject of powerful technologies of massification. Let us remember how the media still exploit trauma and violence to create such figures as the terrorist, the crook, and the immigrant. Let us remember how hegemonic institutions exploit the idea of disgust, to create the figure of the civilized and the uncivilized.

At the same time, discussions about affection bring us to a broader discussion about ethics. Affect as the result of an active relationship, of an intra-action, points out that we are always partially responsible. Affecting and being affected remind us that we affect the world we live in, that we affect the assemblages in which we are present, and that we affect and are affected by affections, by things, people, humans, and nonhumans. We affect and are affected by the apparatus of our discipline, we affect and are affected by the knowledge we generate in an active way. As Barad would say, "Ethics is not concerned with the questions of matter, but rather the very nature of what it means to matter" (2012, 70).

State of Knowledge and Current Debates

Introduction

The Egyptian civilization developed along the banks of the Nile River from the south, from the cataracts, and from the border with present-day Sudan to the delta, from which the river flows into the Mediterranean Sea for a total extension of about 1,000 km. The history of this civilization covers a total of about 4,000 years, though the identification of a specific historical period and agreed dates is still source of debate, especially concerning its temporal location in prehistoric times and the many vicissitudes and dominations that accompanied the history of Ancient Egypt in its final part.

Many cultures followed one another in the Nile Valley since the Predynastic Period, in c. 3,900–3,500 BC. An embryonic stage of the State emerges in the Archaic Period with the First Dynasty (c. 3,200–3,100 BC) and with the unification of Upper and Lower Egypt. These two macro-areas will always remain distinct; in fact Egyptian rulers had among their titles that of *nsw-bjty* "King of Upper and Lower Egypt (see Appia 1996)."

Despite the great extension of the territory, which also included much of the Libyan-Nubian Desert, the ancient settlements developed in the narrow greenbelt near the riverbanks only. Traces of settlement dating back to 3.500 BC, in fact, have been found mostly along the banks of the Nile and, as far as the desert areas are concerned, only near the oases. Thanks to the annual floods and the fertile silt that the river carried, agriculture was prosperous, in particular the cultivation of wheat, barley, and flax. In order to guarantee a regular supply of crops, it was necessary to have control over the waters, to channel and preserve them since ancient times. The annual floods, in fact, allowed to harvest several times a year.

It is precisely this urge to deal with the needs connected with the management of agriculture and nilotic waters that favored the formation of the first communities at some time prior to 3,500 BC. These entities were allocated to partial but well-differentiated territories, politically and geographically identifiable with the Greek term of nomoi (*νόμοι*) that soon evolved into two distinct more complex geopolitical entities (see Grimal 1998; Wilkinson 2010).

The history of Ancient Egypt has been divided into 30 ruling dynasties by Manetho (Egyptian priest and historian under the reigns of Ptolemy I and Ptolemy II, c. 305–285 BC) in his *Aegyptiaca*, in which he also indicated the duration of the kingdom of each king. This subdivision is still used today, albeit with the appropriate modifications given by recent archaeological discoveries. To these 30 dynasties must be added those non-native governments raised from invasions and from the attainment of power by foreign rulers: XXXI Dynasty of Persian sovereigns; XXXII Dynasty of the Macedonian sovereign Alexander the Great; and XXXIII Dynasty, known as the Ptolemaic dynasty, born from the fall of Alexander's Macedonian empire. In addition to the Macedonians, also many Roman emperors who occupied Egypt would call themselves "pharaohs" also assuming the hieroglyphic title (see Cimmino 2003; Dodson and Hilton 2004).

The Ancient Egypt was home of a thriving civilization that through the construction of pyramids, temples, and statues tried to get in touch with the gods and the beings that inhabited the afterlife. Despite the millennial history of Ancient Egypt, after the Arab conquest in the seventh century, the culture, customs, and traditions of pharaonic Egypt were gradually overshadowed by Arab culture. Since the knowledge of the hieroglyphic language was progressively forgotten, and therefore the ancient Egyptian texts could in no way be translated, during the Middle Ages and until the seventeenth century, the Western world had a vision of Egypt totally different from reality.

The interest of the West toward Egypt began with Napoleon Bonaparte's campaign in Egypt and Syria (1798–1801); from this moment on, Egypt assumed a certain charm and mystery. In over a century or so, Egyptologists discovered most of the treasures buried along the banks of the Nile, from the entrances to the pyramids, such as those of the Giza Plateau, to tombs and sarcophagi, such as Tutankhamun's. Jean-François Champollion is responsible for deciphering hieroglyphic writing, thanks to the discovery, during Napoleon's campaign in Egypt, of the Rosetta Stone containing a trilingual text: hieroglyphic, demotic, and Greek. This event marked the birth of Egyptology (see Clauss 2001).

Archaeologies of Egypt

Since ancient times some authors have been interested in Egypt and its customs, developing writings and reports related to them. We have already mentioned Manetho and his contribution to modern Egyptology, but among the other authors, we must first of all remember Herodotus (484–430 BC) who, in the second book of his *Histories*, spoke in detail about the Egyptians and their customs, describing minutely some religious and funerary practices such as mummification. Diodorus Siculus (90–27 BC) in the first book of his *Bibliotheca historica* described the history and geography of Egypt.

Strabo (60 BC–21/24 AD) likewise treated the history and geography of Egypt in his works. Also Pliny the Elder (23–79 AD) in his *Naturalis Historia* dealt with Egypt, although in a less detailed manner than the abovementioned authors. This undoubtedly demonstrates that the fame and charm of Egypt have strongly influenced other ancient cultures, first of all the Greek and Roman cultures, reaching the point of capturing the attention and curiosity of most scholars and historians up until the modern era.

During the Middle Ages, Egypt was not taken into great consideration, returning instead to arouse interest during the Renaissance. The presence of some obelisks found in Rome generated a growing interest in hieroglyphic writing, which at the time was still incomprehensible. Starting from the fascination that Egypt and its monuments aroused, an increasingly scientific interest in Egyptology was gradually formed. Emblematic is the case of the famous *Bembine Table of Isis* (or *Mensa Isiaca* or *Isiac Tablet*) that arrived in Turin around the year 1630 after being bought in Rome by Cardinal Bembo after the sack of the Landsknechte of 1527. It is a bronze table damascened in silver, copper, and niello with images of various deities within a frame in hieroglyphics, now preserved at the Egyptian Museum of Turin. It was probably built in Rome in the first century AD for an Isiac sanctuary; therefore it is an Egyptizing artifact whose hieroglyphics have been engraved without any intrinsic meaning, only as decoration. The *Bembine Table* was carefully studied first by Lorenzo Pignoria and later by other scholars, including the Jesuit Athanasius Kircher, a great scholar and theologian.

The first real step that led from what we can call Egyptomania to the real Egyptology was the Napoleonic expedition that started toward the end of the eighteenth century. The publication in 1809 of the *Description de l'Égypte* (written in 25 volumes) constitutes the first real scientific report; in fact it cataloged and described the monuments and artifacts found during the expedition, including the very famous Rosetta Stone. The study and research conducted on Rosetta Stone by Jean-François Champollion (decipherer of hieroglyphic writing) and Ippolito Rosellini crown the birth of Egyptology as a proper science. They also conducted an important Franco-Tuscan Expedition between 1828 and 1829, followed by that of the German Karl Richard Lepsius between 1842 and 1845.

Of great importance is the contribution of the Italian Giovanni Battista Belzoni, who led a trip to Egypt between 1815 and 1819 visiting and exploring numerous sites. He was the first to enter the Great Temple of Ramses II at Abu Simbel; he discovered six tombs in the Valley of the Kings and opened the entrance to the Pyramid of Chephren in Giza. Many of the finds he found are now kept at the British Museum in London.

In France, important contributions came from the archaeologists Auguste Mariette, founder of the *Service des Antiquités* and the Egyptian Museum in Cairo, and Gaston Maspero who was

his pupil and continued his work. On the British front, we must remember the archaeologist Flinders Petrie, who devised his own technique of serialization of the finds establishing the chronological succession of about 2,200 graves in the necropolis of Naqada (Upper Egypt). The *Egypt Exploration Fund,* today known as the *Egypt Exploration Society*, was brought to life in the United Kingdom in 1882. This organization is responsible for numerous and important expeditions to many archaeological sites in Egypt, including Deir el-Bahari (or Dayr al-Bahri), Tell el-Amarna, Saqqara, and recently Deir el-Medina.

Among the most important discoveries of the twentieth century, we must certainly remember that of the Tomb of Tutankhamun (KV62) by Howard Carter and Lord Carnarvon in 1922.

The contributions of the abovementioned scholars and archaeologists and of many others have turned Egyptology into a science and have allowed the circulation of Egyptological finds throughout the world, leading the foundation of the most important museum collections and university faculties.

Physical Geography

Egypt, with an extension of 1,001,450 km^2, is located in Northeastern Africa. It overlooks the Mediterranean Sea at north and the Red Sea at east for a total coastal extension of about 2,450 km. The Mediterranean Sea and the Red Sea have been connected to each other by the Suez Canal since 1869. The Sinai Peninsula, a region in the east of the country, overlooks the Red Sea and forms the two narrow gulfs of Aqaba and Suez. At the mouth of these gulfs are the Egyptian marine islands of Tiran (80 km^2) and Shadwan (42.5 km^2), in addition to numerous river-type islands present in the Nile Delta.

The Egyptian territory is almost totally desert (about 95%) and can be divided into four geographic regions: in the north, the Nile Valley and its Delta (which covers 4% of the surface), an area with the most favorable environmental conditions for the development of human settlements; to the west, the Western Desert (over $2/3$ of the territory), mostly flat except the more mountainous southwestern part; to the east, the Eastern Desert, between the course of the Nile and the Red Sea, more mountainous than the Western and with heights reaching almost 2,000 m in height; and to the northeast, the Sinai Peninsula, which consists into a small extent of flat areas (which overlook the Mediterranean) and for the most part of hills and mountain ranges that constitute the highest places in the country, including Mount Catherine, which with its 2.641 m height turns out to be the highest peak.

The Nile, the second longest river in the world (6,853 km), crosses Egypt for c. 1,532 km and constitutes, together with the oases, the only fertile area of the country. It enters Egypt from Sudan, just north of the Sudanese city of Wadi Halfa (22nd parallel) and expands to form Lake Nasser. Starting from the south, after the Aswan Dam, the river sums up its natural course by drawing an elongated S that winds from Aswan to Cairo. Along its course (about 850 km), we progressively encounter some of the most important sites in Egypt including Kom Ombo, where the valley widens for about 20 km to then shrinks again, Edfu, El Kab, Hierakonpolis (Nekhen), and finally, Esna where the valley widens again between 8 and 15 km. North of Esna the river curves northeast across Gebelein, Hermontis, Luxor, Karnak, Naqada, Coptos, and Dendera. Here a limestone cliff of about 300 m high forces the river to change direction toward southwest for c. 60 km then continue northwest. The river continues for about 160 km up to Asyut meeting the sites of Kom el-Ahmar, Nag Hammâdi, Abydos, Thinis, and El Badari. After Asyut, the escarpments on both sides of the river decrease in height, the valley widens by about 22 km, and the river heads northward meeting Meir, Amarna, Hermopolis, Tunah el-Gebel, and Beni Hasan up to Beni Suef. The Nile then continues its course through the sites of Herakleopolis, Gurob, Medinet el-Fayyum, Meidum, Gerzeh, Lisht, Iti-tawy, Dahshur, Memphis, Saqqara, Abusir, Abu Gorab, Zawiyet el-Ariyan, Giza, Abu Roash, Cairo, and Heliopolis. From here on, it comes across the sites of Herakleopolis, Gurob, Medinet el-Fayyum, Meidum, Gerzeh, Lisht, Iti-tawy, Dahshur, Menfi, Saqqara, Abusir, Abu Gurob, Zawiyet el-Ariyan, Giza, Abu Roash, Cairo, and

Heliopolis. Near Cairo, the river is divided into various sections, thus giving rise to a large delta whose two main branches are to the east the Damietta (c. 240 km) and to the west the Rosetta (c. 235 km). Among the most important sites of the Delta, we should mention Tanis, Bubastis, Mendes, Iseum, Busiris, Leontopolis, Buto, Sais, Naukratis, Rosetta, Canopus, and Alexandria.

The desert climate presents very high average temperatures and low rainfall. In desert areas, there are frequent strong temperature changes ranging between 0° in winter and 50° in summer.

The Western Desert occupies the part of Egyptian territory that goes from the Nile Valley to the border with Libya and from the Mediterranean to the border with Sudan for an area of about 700.000 km^2. The territory is generally flat and sandy, consisting of desert plains that rise gradually from north to south and reach their maximum height in the southwestern area on the border with Libya and Sudan. What constitutes an important variation of the geophysical conformation of the desert are depressions in the ground, in which the oases develop. The most extensive depression is that of Qattâra, which reaches 133 m below sea level, flanked by the smaller one of Siwa. The Oasis of the Fayyum is much closer to the Nile, from which it receives the waters by means of an ancient artificial canal that allows the development of agricultural crops. Other, less deep depressions are found further south: el-Bahariya, el-Farafra, el-Dakhla, and el-Kharga. North of the depression of Qattâra, the desert degrades on the Mediterranean with low rocky slopes that leave room for a narrow coastal plain. Dates, cereals, and legumes are cultivated in the oases, while along the Mediterranean coast, where in winter, there is also precipitation, and the rare nomadic populations raise camels, sheep, and goats.

The Eastern Desert extends from the eastern band of the Nile Delta to the northeastern Sudan and to the east up to the Gulf of Suez and the Red Sea, with an area of about 222,000 km^2, equal to almost ¼ of the surface of Egypt. The territory consists of a sandy plateau that rises abruptly from the Nile Valley and extends eastward for a width ranging from 80 to 170 km to the so-called Red Sea Hills, a chain of mountains that develop northward south from Suez to the border with Sudan and reach the maximum height of 2.187 m with Mount Shaiyb al-Banat. The Eastern Desert, due to its location, receives more rainfall than the Western Desert.

The Sinai Peninsula, although politically belonging to Egypt, is geographically part of the Asian continent. It is bordered to the east by the Israeli desert of the Negev and the Gulf of Aqaba, to the north by the Mediterranean Sea, to the west by the gulf and the Suez Canal, and to the south by the Red Sea. The peninsula has a length from north to south of about 380 km and a width from west to east of about 210 km, for a total area of 61,000 km^2 approx. The eastern part of the peninsula is known as the Great Rift Valley, and it is a geological pit that extends from the valley of the Jordan River southward through the Red Sea into Africa into Kenya.

Chronology

As already stated above, the chronological scheme still used today to divide Egyptian history is based on the one provided by Manetho, who around 300 BC divided the succession of Egyptian kings into a series of 30 "dynasties," so recognized as belonging each to the same house. Manetho's dynastic succession is substantially in line with our knowledge of the changes in the ruling family, although in some cases, the reason for a dynastic change is not clear. Modern scholars have redefined the chronological structure by grouping the dynasties into "kingdoms" and "periods" during which constant sociopolitical themes can be identified. In ancient times, dating was recorded for years of reign and not as it is today due to the distinction of "epochs" or "periods."

Despite the great difficulty of giving substance to the periods dating back to prehistoric times, the Egyptian chronology is based on a few fixed data from which dates could be obtained. One of these refers to the heliacal rising of Sothis (Sirius), called Sopedet by the Egyptians (*Spdt*). Sothis rises about 30 min before dawn around the summer solstice. Thanks to another well-known event, that is, the rise in Heliopolis on July 21, 139 AD (as indicated by the Roman grammarian Censorinus), it was possible to date the heliacal rising of Sothis:

- In the year 7 of the reign of the Pharaoh Sesostris III of the XII Dynasty: about 1879 BC
- In the year 9 of the reign of the Pharaoh Amenhotep I of the XVIII Dynasty: about 1547 BC
- In the year 20 of the Pharaoh Thutmose III of the XVIII Dynasty: about 1471 BC

From these dates, together with the King Lists (Abydos King List, Saqqara King List, Turin Royal Canon) and other writings of ancient historians such as Sextus Julius Africanus and Eusebius of Caesarea, it was possible to construct a chronology that gave a solid foundation to the studies of many Egyptologists who otherwise would have continued to rely on dating with no absolute value. In recent times, more scientific dating systems, such as C^{14} or radiocarbon, have allowed specific analyses to be carried out on certain findings, allowing scholars to formulate more certain hypotheses regarding the Egyptian chronology. Despite all this, numerous uncertainties regarding the chronology still remain today, in particular as regard the Predynastic Period and the periods for which the sources are more scarce. The chronology provided therein is based on that of Ikram and Dodson (1998) and Shaw (2005).

Archaeology of Ancient Egypt Through Its History

Drawing a complete picture of the archaeology of Ancient Egypt is not a simple work, and an exhaustive treatment of it requires the drafting of one or more monographs. The extraordinary length of its history alone represents a difficulty for the authors who treat it, but even more complex is the close relationship that exists between it and the history of art, archaeology, and the whole complex of religious beliefs and costumes of Egypt. These aspects are effectively inseparable. Therefore, we cannot speak of a "history" of Ancient Egypt without implying the history of its monuments, its culture, and the evolution they have had over a period of more than 40 centuries. On the other hand, however, scholars must make choices and see themselves forced to separate the different Egyptological subjects. The reader must therefore necessarily summarize this work with other texts and essays, which deal with the other numerous aspects of this complex world which is Ancient Egypt. From this derives the title of this paragraph: our intent is to deal primarily with the material culture of Ancient Egypt, giving it a general overview of its main aspects and its evolution through history (Fig. 1).

From Palaeolithic to Predynastic Period (c. 700.000 BP–3.000 BC)

The Nile River was certainly the main fulcrum for the birth and prosperity of Egyptian civilization, and the geographical position of the country favored the first human migrations from East Africa to what we today call "Old World." There are still no reliable data to establish the time when the Nile Valley was occupied by the first human groups (see Schulz and Seidel 1997).

Dating from the *Lower Palaeolithic Period* (c. 700/500.000–250.000 BC) are many artifacts including numerous Acheulean handaxes. These artifacts are not connected to human remains. However, they could have belonged to the groups of Homo erectus allocated there and date back to the period between 400.000 and 300.000 BC. The main places of discovery of these findings are the hilly area between Deir el-Medina and the Kings Valley, Nag Ahmed el-Khalifa (near Abydos), and the region of Qena, where the concentration of handaxes is found on the first deposits of clay that indicate a connection with its sources in Ethiopia. In the Western Desert, the best-known Acheulean sites are the oases of Kharga and Dakhla, Bir Sahari, and Bir Tarfawi. The climatic conditions of these sites, where the humidity was higher, favored the establishment of groups of hunter-gatherers. The poor state of conservation of these sites, as well as the lack of detailed archaeological investigations, makes it impossible to provide an exhaustive documentation. Also in Nubia, a conspicuous quantity of handaxes and Acheulean lithic artifacts has been found, but their dating is uncertain and is based only on typological data.

The *Middle Palaeolithic Period* (c. 250.000–70.000 BC) presents some elements of continuity with the Acheulean (like the presence of handaxes) but also the introduction of important innovations in the production of lithic artifacts, such as the Levallois technique. Numerous sites

Archaeology of Ancient Egypt, Fig. 1 Prehistory and Predynastic Period chronology

Period	Phase or Culture	Dates
Palaeolithic Period	Lower Palaeolithic	c. 700.000 – 250.000 BC
	Middle Palaeolithic	c. 250.000 – 70.000 BC

	Naqada III Culture or Dynasty 0	c. 3.200 – 3.000 BC

dating back to the Mousterian period have been identified as excavated near Bir Sahari and Bir Tarfawi in the Western Desert. The alternation of warmer periods in summer and colder periods in winter leads us to suppose that the occupation of these sites was mostly seasonal, and their location was certainly chosen based on the proximity to the places of extraction of raw material, used for the manufacture of instruments. Even in the Nile Valley, there were sites of this type, and undoubtedly many of the artifacts produced at the same mining sites also circulated elsewhere, arriving at other more distant settlements. At least two different processing techniques have been recognized, one of classical Levallois type and the other of Nubian Levallois type. The period defined Aterian (c. 70.000–50.000 BC) follows the Mousterian and is characterized by the use of the bow.

The sites of the *Upper Palaeolithic Period* (c. 50.000–24.000 BC) are rare in Egypt. The oldest is Nazlet Khater, where skeletal remains of an individual were found between 1980 and 1982. This site is also one of the oldest examples of underground mining activity in the world. The lithic industry shows no traces of Levallois technique, and the instruments are mainly scrapers, chisels, denticulates, double-sided slats, and double-sided axes. The next phase is that of the Shuwikhatian industry, attested in several sites near Qena and Esna. It is characterized by the presence of sturdy blades, toothed blades, and scrapers.

Unlike the previous period, many sites of the *Late Palaeolithic Period* (c. 24.000–10.000 BC) have been discovered in the Upper Egypt. During this period, the climate became more arid, and the Nile River began to contain less water and more clay, especially in its springs. The oldest sites are the Fakhurian (c. 21.000–19.500 BC) and the Kubbaniyan (c. 19.000–17.000 BC). The latter

was located not only near Wadi Kubbaniya (near Aswan), from which it takes its name but also near Esna and Edfu. The occupation of these sites was not continuous but seasonal and was due to the nature of the food supply. The Fakhurian group presents four main classes of instruments: backed bladelets (which constitute the largest percentage), end scrapers, burins, and truncations. Of great interest at this stage are the first attestations of rock art in the Nile Valley, especially Abka (near the second cataract) in the "site XXXII," and in el-Hôsh, south of Edfu, whose depictions represent fishing. Between 16,000 and 12,000 BC take turns different industries: Ballanan-Silsilian (16.000–15.000 BC) characterized by the microburin technique; Afian (12,900–12,300 BC) of which the Nilotic site of Makhadma presents important traces of fishing techniques; Isnan (12,300 BC) characterized by the rough knapping technique; Qadan (12,000 BC) associated with three necropolises (the most notable being that of Gebel Sahaba, from which 59 skeletons originate) with pit tombs covered with sandstone slabs; and Sebilian, from the uncertain chronology, whose lithic technology (with prevalent use of quartzite or volcanic rocks) is different from other cultures of the period, perhaps an indication of intrusive groups coming from the south.

The following period, *Epipalaeolithic period* (c. 10.000–8.000 BP), is characterized by a chronological hiatus in the occupation of the Nile Valley. There is indeed no evidence of human presence between 11,000 and 9,000 BC, except for some small Arkinian sites in the region of the second cataract, datable to 9,400 BC. This is perhaps due to a drying up of the entire Nile Valley. However, the climatic conditions were not so dry as to make the fertile Nile Valley inhospitable. Following a climatic overheating and a consequent increase in humidity, there were numerous floods and frequent precipitations that favored the development of new settlements in the oases rich in water between the VIII and VII millennium BC, in full *Neolithic Period* (c. 8.800–4.700 BC). In this period, the lifestyle of human groups changed considerably, attracted by the fertile areas and began to abandon the nomadic life, passing to a semisedentary lifestyle. These groups hunted and harvested seeds and grasses; they even started taming cattle. It seems that the influences deriving from the Near East, in particular from the Syro-Palestinian area, played a fundamental role in the introduction of the first agricultural techniques toward the middle of the VI millennium BC.

The period that separates the Epipalaeolithic from the Neolithic is little known. We know that a new sub-pluvial period favored breeding and agriculture on the edge of the Nile Valley and in the area of western oases. We are witnessing the progress of weaving techniques and the production of ceramics. From the middle of the VII millennium BC to the middle of the V millennium BC, we witness the birth of all those cultural elements that will remain unchanged until the end despite the appearance of metals.

In any case, in this period, we distinguish two distinct phases in the Nile Valley which intersect chronologically. These phases correspond to the cultures that developed during the *Predynastic Period* (c. 5,300–3,000 BC) in the Lower and Upper Egypt.

As far as Lower Egypt is concerned, the oldest Neolithic culture is that of *Merimda* (Beni Salama) whose site, located in the western area of the Delta, has at least five settlement phases ranging from 5,200 BC to around 4,500 BC. Among the most important attestations, there are plates, bowls, and cups made of the finest ceramic with herringbone decorations. There are also arrowheads, bone harpoons, and nubian stone axes that demonstrate contact with the south. It is precisely with Merimda that the progressive changes that led from the Palaeolithic to the Neolithic are affirmed. Among them, we have the transition to a sedentary lifestyle, with the development of settlements mainly devoted to agriculture and breeding and characterized by ceramic innovations and, therefore, to the progressive formation of a new class of artisans. Moreover, in this period, the first contacts and commercial exchanges with the Syro-Palestinian area are recorded. Numerous pit graves were also found in Merimda where the deceased were placed in a fetal position. Only in some cases have the materials supplied been found, but from them, no social distinction emerges between individuals.

However, from the excavations, it emerged that in the long period of site settlement, the later inhabited areas overlapped the areas previously used for burials.

The most recent phase of the Neolithic cultures of Lower Egypt is represented by the site of *Maadi*, southeast of Cairo, corresponding to the first two thirds of the IV millennium BC. The urban settlement is annexed to two necropolises, and the material culture includes ceramics, tools in copper (needles, blades, and axes) that have replaced those in bone, and traces of copper ore probably used as a dye for cosmetics. The discovery of high Egyptian ceramics and other materials from the Syro-Palestinian area shows that Maadi must have been an important crossroads for trade and commerce between the Asian area, the Nile Valley, and Upper Egypt. The necropolises of Maadi testify to rather summary funeral rites: the dead were placed in shallow oval pits, covered with mats, accompanied by a few items of furniture (clay pots and sometimes shells).

As far as Upper Egypt is concerned, the oldest Neolithic culture was that of El Badari (hence the definition of *Badarian culture*), which probably originated in the Western Desert. According to Jean Vercoutter, the Badarian culture arose between 4,400 and 4,000 BC, but it would be likely to assume that it had arisen around 5,000 BC. It was known in particular for the high quality of its ceramics, its stone tools, and the use of copper. Among the most noteworthy aspects are the numerous burials and the rich funerary objects found in them, as they not only demonstrate a remarkable artisan quality but allow for the first time to determine the social status of the dead. While the ceramics of daily use were mainly large vessels, those present in the burials were much finer. Plates and bowls often had a red and brown color whose most characteristic element was the type of decoration with a rippled surface as it was "combed" in order to give a wavy and shiny appearance. The typology of the Badarian burials constitutes the first manifestation of the development of the funerary practices that will be affirmed in the following epochs in Upper Egypt. The dead were buried lined up in oval tombs, in a fetal position on the left side and looking west. They were usually wrapped in mats with rich funerary furnishings alongside; in the tombs besides the ceramics, there were jewels, furnishings for personal care, ivory and bone carvings, and objects with figurative decorations. Several other objects also appear, such as the stone palettes for the blasters, carved wooden spoons for the ointments, brooches, bracelets in bone and ivory, necklaces with turquoise beads, precious combs, enamelled soapstone, shells, different types of stones, and, rarely, also needles and pearls made of copper.

Immediately after the Badarian culture is the *Naqada culture* which takes its name directly from the Naqada site, conventionally divided into three periods: *Naqada I* (c. 4,000–3,500 BC), or *Amratian Period* from the site of El-Amra (first site where this cultural group was discovered), characterized by the production of black-topped vases and the introduction of ceramics decorated with white parallel lines and by the first attestations of the import of obsidian from Ethiopia for the manufacture of blades; *Naqada II* (c. 3,500–3,200 BC), or *Gerzean Period* from the site of El-Gerzeh, in which are recorded the first attestations of contacts with the Near East, in particular with Canaan and the coast of Biblo; and *Naqada III* (c. 3,200–3,000 BC), or *Dynasty 0*, a period that sees the formation of the Egyptian state taking place. This period is called Dynasty 0 since we have only the names of some sovereigns at the head of independent kingdoms who were fighting to dominate the region. This is a period of technological, social, and political innovations.

The *Naqada I* culture, about 120 km south of El Badari, developed at the beginning of the IV millennium BC (ca. 4,000 BC) parallel to the Badarian culture, the two merged, and then the Naqada culture replaced the Badarian culture. The places of origin and diffusion are located further south than the Badarian ones: in the area between Luxor and Abydos, an area where the main communication routes intersected with the East, the Red Sea, and the oases. Also from an environmental and technological point of view, the Badarian and Naqada I cultures are similar, even if the latter presents some peculiarities. Among the ceramics, the black-topped vases predominate, characterized by red walls and a black-colored

rim, and red ceramic with cream-colored decorations that had geometric motifs at first and figurative later on. Among the latter are the representations of the fauna of the Nile Valley, especially crocodiles and hippopotamuses, and depictions of hunting scenes or even war scenes. Of great importance are the depictions of boats that will be characteristic even in the full Pharaonic era. Alongside the ceramics, there are more figurative subjects such as feminine idols, pendants depicting male individuals with beards, and ivory sticks, all objects belonging to the symbolic sphere. Other typical objects of the Naqada I culture are the shale palettes in rhomboid shape and the mace-heads, recurrent objects in the high-born male burials. Predominant feature of the populations of this period is the territorial expansion from the area of Qena northward to the area between Asyut and the Fayyum and southward beyond the first cataract (Fig. 2).

The *Naqada II* culture began to be recognized toward the middle of the IV millennium BC. In this period, the production of black-topped ceramics ended in favor of new techniques: production of clay pots from the Nile mixed with straw and the use of a new type of clay, the marl, coming from the calcareous formations of the hills bordering the valley. The clay from the Nile is first used for the production of rudimentary shapes, tubs, and silos and then for the production of a wide range of better quality ceramic shapes. From the marl, more difficult to process, a hard and thick quality ceramic was produced for the production of containers for long-term storage of food. Furthermore, marl was used for the production of new types of objects: small- and medium-sized vases, pot-bellied, or conical, often with handles. The decoration has purely geometric motifs but also dots or spirals. It was done with a brush with a dark red or brown paint on a cream-colored background. There are also decorations depicting, although in a stylized manner, local flora and fauna. The main feature of distinction between the Naqada I and Naqada II periods is the greater quantity of decorations present on the Naqada II ceramic, as well as a higher quality of the ceramic productions. It is interesting to note that some typical symbols of Naqada II ceramics resemble some signs of traditional hieroglyphic writing and are contemporaries of pre-cuneiform Sumerian writing. A distinctive characteristic of this period is the type of settlement patterns that developed: in fact, alongside the rural areas, the first urban agglomerations were formed, the first "cities." The presence of fences of temples and fortifications is also documented, and in the inhabited centers appear traces of a specialized handicraft. The burials became larger and rectangular with walls in masonry or with wooden reinforcements, and the first side chambers appeared for the storage of the trousseau that became ever richer. Not all the tombs contained a rich collection, and this certainly proves the social gaps of that period (see Dodson and Ikram 2008). Certainly, the remarkable artisanal development of this culture went hand in hand with an improvement in agricultural techniques, which also allowed the production of a surplus that was accumulated and kept in an increasingly systematic way. Thus, we witness the establishment of the first social elite and the establishment of an institutional authority that can be considered the basis of Egyptian royalty. The Naqada II period ends with the formation of the first kingdoms in Upper and Lower Egypt.

Archaeology of Ancient Egypt, Fig. 2 Example of black-topped ceramic vase

The period of the *Naqada III* culture corresponds to the phase in which Egypt was for the first time unified in a larger territorial state. The

consolidation of a central power is found, in fact, in what is called *Dynasty 0*, immediately preceding the first two dynasties defined as "Thinite." But we must keep in mind that in this period, we cannot yet speak of a true unified State, since well-defined political-territorial entities were emerging but only at the local level. From the evidence of elite burials in the three major predynastic centers of the Upper Egypt, namely, Naqada, Abydos, and Hierakonpolis, one can highlight a first unification of Upper Egypt as a result of a series of alliances or conquests of war or perhaps both. It is interesting to note that in the larger elite pre-dynastic cemetery of Naqada III, there is an evident impoverishment of burials compared to the previous Naqada II period, probably caused by the political changes that occurred during the transition between the two phases. On the other hand in the region of Umm el-Qa'ab, near Abydos, burials seem to have evolved from the Naqada II period, becoming a veritable elite cemetery. According to Günter Dreyer, a burial there was supposed to belong to the famous King Scorpion II, whose name is known to us from some finds and who ruled between about 3,100 and 3,000 BC. The head of the Scorpion King's club was found in Hierakonpolis, the same place from which the palette and mace-head of King Narmer come. These three objects could be identified as royal donations to the temple of Hierakonpolis, and this suggests that this center had a particular importance during the Naqada III period. Although doubts remain, it seems likely that the site of Naqada gradually lost its importance in favor of the centers of Abydos and Hierakonpolis from which, through military alliances or conquests, there was a first reunification of Upper Egypt and due to Narmer (conventionally considered the first ruler of the I Dynasty) was completed the first unification of Upper and Lower Egypt. It is from this moment that the rulers of Egypt used the royal titles: the Name of Horus (*serekh*), the Name of the Two Ladies (*nebty*), and the Name of the Ruler of the Two Lands (*Nesu-bity*) (Fig. 3).

From the Early Dynastic Period to the First Intermediate Period (c. 3.000–2.055 BC)

The first dynasties defined by Manetho Thinite from the city of **Thinis** near Abydos date back to the *Early Dynastic Period* (c. 3,000–2,686 BC). With the birth of the I Dynasty (3,000–2,890 BC), those customs and values that characterized the Egyptian civilization for many of the centuries to come begin to assert themselves, first of all the adoption of the hieroglyphic writing, whose first prototypes are found in the recovered finds of the royal necropolis of Abydos. In fact, most of the kings of the Thinite Dynasties can be found in Abydos but also around Memphis. The documentation in our possession for this period is mainly based on these necropolises, the Royal Tomb of Saqqara and on some other documents such as the Palermo Stone and the Canon of Turin (see Schulz and Seidel 1997).

Archaeology of Ancient Egypt, Fig. 3 Early Dynastic, Old Kingdom, and First Intermediate Period chronology

Period	Phase or Culture	Dates
Early Dynastic Period	I Dynasty	c. 3.000 – 2.890 BC
	II Dynasty	2.890 – 2.686 BC
Old Kingdom	III Dynasty	2.686 – 2.613 BC
	IV Dynasty	2.613 – 2.494 BC
	V Dynasty	2.494 – 2.345 BC
	VI Dynasty	2.345 – 2.181 BC
First Intermediate Period	VII/VIII Dynasty	2.181 – 2.160 BC
	IX/X Dynasty	2.160 – 2.025 BC
	XI Dynasty (Thebes)	2.125 – 2.055 BC

Some of the most significant finds of this period are the makeup palettes, ivory knife handles, and, above all, the mace-heads of which the most famous is certainly the Narmer Palette (see Stevenon Smith 1998). This document summarizes in itself the unification of Egypt bearing the name of the king Narmer, represented on one side wearing the white crown of Lower Egypt and in the act of demolishing an enemy and on the other side visibly larger than the characters in the register wearing the red crown of Upper Egypt, in the act of inspecting the decapitated bodies of the enemies (Fig. 4).

One of the greatest expressions of Egyptian royalty is found in the development of a new funerary architecture. The necropolis of Abydos rises about 1.5 km from the fertile areas and consists of oblong chambers carved into the depths of the desert soil whose walls are reinforced with brick walls. The first phase belongs to the time of the Horus Aha (which some Egyptologists believe to be the same as Narmer) whose burial, unlike the previous ones, consisting of two chambers, consists of three much larger funerary chambers. It also begins the custom of burying the entourage of the king (whose members seem to have been killed during the funeral ceremony of the king) in nearby burial chambers whose use, however, lasts until the end of the I Dynasty. The funerary complex of his successor Djer presents structural innovations at the base of which there are later developments. In particular, to the numerous burial chambers, it is preferred a single larger chamber. Some traces reveal that the king must have been deposed in a wooden coffin. In any case, these are real mounds whose external features, however, remain unknown, perhaps because they were no external superstructures. Only a few steles remain, bearing the names of the kings, who were probably to be placed in places of worship before the burial. King Den introduced the use of an access ladder (usually southwest) to the burial chamber, sealed by boulders, and a chapel with his statue, the living could address their prayers to the statue from which the king could symbolically come out.

Archaeology of Ancient Egypt, Fig. 4 Narmer Palette. On the left the king wears the red crown; on the right he wears the white crown

In addition to the funerary complexes, the remains of imposing rectangular complexes located about 1,5 km away from the necropolis of Abydos have been found. The imponent funerary complex of Djer presents an architectural style that undoubtedly refers to the subsequent pyramidal complex of Djoser (III Dynasty) in Saqqara (see Lehner 1997).

Some sovereigns of the First Dynasty had funeral temples also dedicated to Memphis, as this center gradually acquired great importance until it became the new capital of the kingdom, as well as a royal residence. From archaeological evidence, we can confirm that its founder was Menes.

A major turning point in Egyptian funerary architecture came with the construction of the so-called mastaba tombs. Those found at Saqqara are certainly more impressive than the burials found in Abydos, but it is still not clear where they originated from. Although the remains of the imposing Djer's ruler structures could constitute a prototype, the structures of the mastabas seem to have more points in common with the architecture of the Near East. The niche facades of the Saqqara tombs, in fact, refer to a nearby eastern architectural model and have a low base where there were placed clay heads modeled in clay. At one of the niches in the eastern part of a mastaba, a stele was found which shows the seated sovereign with his title inscribed: it would be a forerunner of the Old Kingdom false-door stele. The Saqqara niche mastabas and the Abydos necropolis still have

common elements: the formal development of the substructure (burial chamber) and of the superstructure (chapel), the presence of external steps, and the presence of secondary tombs surrounding the main one. From this last element, we can recognize the existence of a ruling class that supported the sovereigns and that represents one of the main differences with the Predynastic Period. Among the funerary objects, stand out furniture and everyday objects in ivory and precious wood finely carved next to stone vases of various shapes.

The tombs of the first kings of the II Dynasty (2,890–2,686 BC) are located in Saqqara. The necropolis of Hotepsekhemwy is particularly impressive, but only the underground part of it remains. It has a different structure than the previous ones, as it is used to contain a vast set of furnishings, including furniture, dishes, and food that would have served the deceased in the afterlife. A consolidation of the idea of the tomb as a dwelling for the afterlife can therefore be seen. Subsequent kings of the dynasty (except Peribsen and Khasekhemuy who rejoined the ancient tradition) abandoned the necropolis of Abydos, perhaps because they intended to approach the seat of central power.

The dynasties from the III to the VI date from the *Old Kingdom* (2,686–2,181 BC). The most characteristic element that is introduced in this period, as well as perhaps the main symbol of the entire Egyptian civilization, is the birth of the pyramids.

The first great pyramid is that of the king of the III Dynasty Djoser, in Saqqara, whose stepped structure makes it immediately recognizable. In fact, however, the entire complex represents a great novelty compared to the past, as it combines in itself both the structural form of the mastaba and the new pyramidal structure of which it constitutes the prototype. The pyramid appears to be surrounded by ceremonial structures and decorative structures made here for the first time as the pavilions, the arcades, the fluted columns, the aedicules, the propylaea, the pilasters, and the capitals with pendulous leaves (which will no longer be used in the successive complexes). For the construction of the complex, limestone was used, and the boundary wall, which protected it as a fortress, was the simplified replica of the White Wall of Narmer. The most obvious innovation is the north-south orientation of the complex with respect to the four cardinal points. Below the stepped pyramid there is a labyrinth of corridors, chambers, and galleries connected to a central shaft with the burial chamber which is located between these spaces sealed by a stone as in the burial chambers of the rulers of the Thinite dynasties. Some shafts in the eastern part of the pyramid were used as cenotaphs for the kings of the I and II Dynasties which contained parts of the trousseau including vases and bowls made from precious stones bearing the names of the sovereigns (Fig. 5).

The pyramid of Djoser, rich in numerous symbologies, is the prototype for the subsequent

Archaeology of Ancient Egypt, Fig. 5 Step pyramid of Djoser, Saqqara

funerary complexes to the point that many kings will have one erected. Emblematic was the case of Sneferu (first ruler of the IV Dynasty) who even had three of them built. A first pyramid was that of Meidum, which followed the tiered model of Saqqara. Subsequently, Snefru had it reworked making it pyramidal, but in Roman times, the covering was removed to produce plaster, making its construction phases visible. The other two are in Dahshur. One of these is called the "Rhomboid Pyramid" as it presents a different inclination of the faces in the middle of the height; this change is of extreme importance for the architectural evolution of the pyramids as it marks the transition from the ancient stepped to those of canonical structure that can also be found in the Giza complex. The other pyramid, called the "Red Pyramid" (for the limestone bricks containing iron), was used by Sneferu as his burial and represents the first pyramid of perfect shape. The remarkable technique used to build it makes it one of the most successful examples of the Old Kingdom. Moreover, with Snefru, the orientation of the funeral complex changed from north-south to east-west, due to the identification of the sovereign with the cycle of the sun.

Another very important monumental complex, that of Giza, belongs to Snefru's successors: Khufu, Khafra, and Menkaure. The Pyramid of Khufu is the oldest and largest of the three main pyramids of the Giza necropolis and is by far the most perfect specimen that was never reached by any other pyramid. The pyramid has been extensively studied: it consists of a base of 230 m and is about 146 m high, but originally it must have been higher, as it was surmounted by a pyramidion perhaps in granite. The site of Giza was chosen because the terrain was much better than in Dahshur. Its construction took over 20 years, and it has several rooms inside. The upper sepulchral chamber, covered in dark red granite, must have been the site of Khufu's eternal rest. Inside the pyramid there are ascending and descending corridors, a chamber called "of the Queen" and another called "of the King." Then there are rooms with numerous graffiti bearing the name of Khufu. There are also fake corridors that lead upward, assumed to be ventilation ducts, or perhaps telescopes pointing to the sky.

Khafra's next pyramid faithfully reflects the model of Khufu but is slightly smaller as the one of Menkaure, whose dimensions are about half that of Cheops. Far more characteristic of Menkaure is the sphinx that portrays him in the Giza complex, whose figure has aroused interest and curiosity in all those who have seen it over the centuries (see Bard 2015).

The pyramids of the V and VI Dynasty maintain the Giza model but without managing to reach its grandeur. The choice of the king Shepseskaf, who decided not to build a pyramid but a massive mastaba in Saqqara, is an exception. This return to the past could be seen as an indicator of the difficult political passage that led from the IV to the V Dynasty. Although considerably smaller, there are also numerous pyramids dedicated to the queens. The pyramids that are found along the course of the Nile are very many indeed since they were built systematically during the Old and the Middle Kingdom, but many of them are today almost completely destroyed. We must necessarily mention the pyramid of Unas, the last ruler of the V Dynasty, as it is the first that presents the interior walls covered with funerary texts, the so-called Pyramid Texts.

Another structure of great importance during the Old Kingdom is that of the solar temple. In terms of monumentality, it approaches the pyramid, but it is not a sepulcher but a cultic structure. All solar temples are located between Abusirand Abu Gorab. The solar temple of Heliopolis is the most famous; unfortunately there are no remains to be observed. To get an idea of its features, we can look at the solar temple of Nyuserre in Abu Gorab, which had the same structure. Solar temples are generally composed of the same elements as the pyramid complexes. People could access to the temple of the valley, located lower down, through an uphill ramp. The walls were covered by the decrees that defined the offers. The ramp conducted to an elevated structure which represented a solar boat. At the center of this open-air court, there was an altar placed in front of the image of the *benben* that in Heliopolitan theology symbolizes the incarnation of the creator sun: a trunk obelisk placed on a wide podium. Among the wall reliefs, there are often scenes from the *sed* party.

Archaeology of Ancient Egypt, Fig. 6 Middle Kingdom, Second Intermediate, New Kingdom, and Third Intermediate period chronology

Period	Phase or Culture	Dates
Middle Kingdom	XI Dynasty (whole Egypt)	2.055 – 1.650 BC
	XII Dynasty	1.985 – 1.773 BC
Second Intermediate Period	XIII Dynasty	1.773 – after 1.650 BC
	XIV Dynasty	1.773 – 1.650 BC
	XV Dynasty	1.650 – 1.550 BC
	XVI Dynasty	1.650 – 1.580 BC
	XVII Dynasty	c. 1.580 – 1.550 BC
New Kingdom	XVIII Dynasty	1.550 – 1.069 BC
	Ramessid Period	
	XIX Dynasty	1.295 – 1.186 BC
	XX Dynasty	1.186 – 1.069 BC
Third Intermediate Period	XXI Dynasty	1.069 – 945 BC
	XXII Dynasty	945 – 715 BC
	XXIII Dynasty	818 – 715 BC
	XXIV Dynasty	727 – 715 BC
	XXV Dynasty	747 – 656 BC

The most imposing monuments certainly belonged to the kings, but even the dignitaries of the court and the rich private could enjoy sumptuous burials. However, the main form of the graves of these characters was the mastaba.

The *First Intermediate Period* (2,181–2,055 BC) is characterized by numerous disorders that led to a disintegration of the central power that was restored only after more than a century. Beyond the historical vicissitudes, we can say that the same figurative canons of the previous periods still remained, and the handicraft productions certainly did not stop. A situation of greater difficulty led to the use of poorer materials, so instead of stone it used wood only. In the necropolis of the princes of Asyut, abundant wooden materials have been found including a statuette of Chancellor Nakhti, considered a very fine specimen. This shows that the technical skills, although penalized by a lack of materials, continued to evolve (Fig. 6).

From the Middle Kingdom to the Third Intermediate Period (2.055–656 BC)

The XI and XII Dynasties date back to the *Middle Kingdom* (2,055–1,773 BC) and correspond to a period of recovery of the State. Probably the greatest expression of the architectural monumentality of this period can be seen in the complex of temples erected by Montuhotep II in Deir el-Bahari. It partly takes up the structure of the Old Kingdom funerary complexes, as it has a pyramid inside, but it is included in the complex. It could be defined as a combination of the templar specimens of the past and those that followed it. The peculiar aspects of this temple are represented by the colonnades placed at the limits of the terraces, which are inspired by the saff tombs (hypogeum characterized by a pillared facade with one or more entrances that allowed access to numerous rooms reserved for the sovereigns and their family) of the XI Dynasty, and the presence of

Archaeology of Ancient Egypt, Fig. 7 Coffin of the Middle Kingdom

the first hypostyle hall built in stone. The reliefs found on the walls of the terraced temple contain familiar themes: these are propaganda scenes designed to enhance the figure of the king, such as the pharaoh in the form of a sphinx who defeats his enemies or hunts (see Robins 1997) (Fig. 7).

Among the monumental works dating back to the XII Dynasty, we can remember the pyramids that Amenemhet I and Sesostris I had built at Lisht. The first takes up the prototypes of the VI Dynasty using stone blocks from the Abusir and Giza quarries; the second was built within a stone wall reinforced by a second brick wall and larger than the previous one, although made with a less expensive construction technique. Amenemhet II also had a pyramid built at Dahshur, and his successor Sesostris III did the same. Amenemhet III, on the other hand, had a simple cenotaph built at Dahshur.

During the Middle Kingdom some of the main features of the Egyptian statuary were consolidated, which in part resumed the characteristics of the Old Kingdom, but in a more evolved and diversified manner. Also the use and the shapes of the sarcophagi went through an evolutionary phase which however in this period still presents a remarkable simplicity compared to the much more elaborated and finely decorated models of the New Kingdom and the Third Intermediate Period.

The Middle Kingdom is considered the *classic period* par excellence of Ancient Egypt, although it is neither the longest nor the best documented (see James 2005). Certainly, the hieroglyphic language of this period is an example of it, since many of the most well-known literary texts were composed in this language, which was systematically used for many centuries to come even in monumental inscriptions. Another important feature of this period is the appearance of *ushabti*, mummiform figurines in stone, wood, or faïence. These were "responding statuettes" destined to obey the deceased's orders in the afterlife and to take care of his tasks on his behalf. The presence of some inscriptions bearing the name and genealogical information of the deceased allows us to associate some of these objects to a specific client.

From the XII Dynasty, these statuettes also offer formulas appear. Another group of objects that is found in the funerary objects of this period is one of the statuettes of the servants depicted performing a specific activity. Unlike the ushabti, which replaced the deceased, these served the same function as the funerary paintings: to ensure the life of their lord in the afterlife, his supply and to guarantee him, by serving and entertaining him, an existence worthy of his social class.

The *Second Intermediate Period* (1,773–1,550 BC) is much more documented than the First Intermediate Period and is characterized by the rise of the two dynasties of the Hyksos (XV and XVI Dynasties) which progressively conquered Egypt and became the new kings. Although this is a period conventionally considered as a succession of disorders and strong political changes, there is no lack of attestations of the activity of monumental works. Some kings of the XII Dynasty had already built buildings: Sekhemra-Khutaui in Deir el-Bahari and in Medamud; Sobekemsaf I a Medamud, Abydos, Karnak, Tod, and Elefantine; Sobekhotep III built a colonnade and doors in the temple of Montu in Medamud. Several graves of them and other kings have also been found.

The Hyksos dynasties, contrary to popular belief, favored the construction of other temple complexes, statues, and reliefs, and maintained

commercial contacts with their native homeland, the Levant, but also with various populations of the eastern Mediterranean. Many scarabs have been found of them that carry very special motifs, but perhaps one of the elements that most characterize their cultural identity are the so-called Hyksos fortresses (one of the most important was located outside Egypt in Sharuen, in Palestine). They also introduced the horse, the war chariot, the curved sword, helmets, and breastplates, and their material culture seems closely related to that of the Middle Bronze Age II of Palestine.

Of the XVII Theban Dynasty, partly contemporary to that of Hyksos, we know that it did not have access to great economic resources; however Sobekemsaf II had significant structures erected in Karnak and Abydos, and his tomb, mentioned in the papyrus Abbot, Ambras, and Amherst-Leopoldo II, had to contain a rich funeral kit. There are also numerous seals and burials of this dynasty.

The *New Kingdom* (1,550–1,069 BC), which corresponds to the XVIII, XIX, and XX Dynasty, is the period that can be defined as the most florid and significant of all Egyptian history. Handicraft productions gradually reached an increasingly high artistic and technological level, not only found in ceramics and everyday objects but also and above all in the evolution of coffins and sarcophagi, whose typologies changed hand in hand with the cultic and religious ideology. Thus, we are witnessing changes both in the forms (from a rectangular box to an anthropoid case) and in the ever more elaborate decorations and materials of great value such as gold and Egyptian blue. In the same way, the monumentality and grandeur of the templar complexes reached peaks that are not reflected by any in later periods, just think of the temples of Karnak, Luxor (see Bongioanni 2009), and Deir el-Bahari.

The high Egyptian city of Waset (Thebes) became, in this period, the main center of worship in Egypt. This is where the New Kingdom rulers build their tombs and temples. Karnak developed as a true temple city, consisting of numerous places of worship and sacred streets with small ports for boat stops, palaces, administrative complexes, and warehouses. The area of Karnak included three large complexes: in the center, the enclosure dedicated to Amon-Ra, to the south, the enclosure dedicated to Mut, and to the north, the enclosure dedicated to Montu. The sovereigns of the New Kingdom systematically pledged to expand and embellish the Temple, which is why they are unable to reconstruct the first stages of the interventions (Fig. 8).

The temple complex of Luxor was considered the residence of the god Amon-Ra and the place of regeneration of the divine forces. Even here, it is difficult to date the oldest buildings, but it is certain that the Thutmosid kings erected a large temple. Of great interest is the discovery of a tripartite boat station in the large courtyard of Ramses II that was to serve to house the boats of the divine triad of Karnak: Amon, Mut, and Khonsu. The papyriform red granite columns of Hatshepsut were reused by Ramses II who also affixed his name to it. Amenhotep III replaced the Thutmosid temple with a grandiose sanctuary consisting of a colonnade that allowed access to a south-facing courtyard from which a slightly elevated hypostyle hall opened. Here were the colossal statues of Amenophis III, which Ramses II later moved to his own courtyard. The most sensational find there is a statue of Amenhotep III standing on a sled. From the era of Ramses II, only one obelisk remains (the second was brought to Paris in 1836 and still today is located at Place de la Concorde), three statues and fragments of other statues scattered on the ground (Fig. 9).

In the XVIII Dynasty, the conception of the funerary temples changed; in fact, they were not built near the tomb anymore but on the edge of the desert of the Theban necropolis. These buildings became not only funerary buildings but also places of worship in which to venerate Amon-Ra and the seat of the cult of the king. The first funerary temples were built in Deir el-Bahari, where the funerary temple of Hatshepsut stands out, next to that of Mentuhotep II. Characteristic of this temple are the architecture and the iconographic program whose themes were to ensure worship, divine assistance, designation and legitimation, the aspiration to regeneration in the beyond, and the perpetuation of creation. Another important temple was that of Medinet Habu,

Archaeology of Ancient Egypt, Fig. 8 Papyriform pillars of Karnak

identified with the primordial hill, where the god Amon-Ra-Kamutef was worshiped and whose form allowed the god to continually regenerate (Fig. 10).

A special moment during the XVIII Dynasty was the foundation of Tell el-Amarna. This city was founded by the king Amenhotep IV (Akhenaten) who favored a religion based only on the cult of the god Aton. German and English Egyptologists during their investigations on the site found exceptional works of art. Although the temples and palaces are almost completely destroyed and the figures reduced to fragments, parts of the painted floors, fragments of paintings, reliefs, majolica, and statues have been preserved. In the residential quarters, real works of art were discovered as domestic altars with images of the royal family illuminated by the rays of the sun, sculptural models, and unfinished statues coming from the laboratories of the artisans.

In Qurna, west Thebes, Seti I (XIX Dynasty) had a sandstone temple built which served as a model for all subsequent funerary temples. The temple is surrounded by a high wall of white bricks with protruding quadrangular towers that recall the architectural construction of the Djoser era. A new element of the complex is the addition, in the facade of the temple, of a portico of papyrus-shaped columns that makes Seti I stand out from the previous dynastic tradition. But the most important complex of the XIX Dynasty is undoubtedly the Ramesseum, built by Ramses II, while, at the XX Dynasty, the Temple of Medinet Habu of Ramses III. The peculiarity of these

Archaeology of Ancient Egypt, Fig. 9 Coffin of the New Kingdom

temples lies in the iconography of the decorations: scenes of war in which the king stands victorious over defeated enemies.

The kings built their tombs in the Kings Valley. Near this necropolis, there was also a village of artisans: Deir el-Medina. Of great importance is the decorative program that first involved only the walls and pillars of the burial chamber, the antechamber of the shaft, and later, in the Ramesside period, the entire complex is decorated with representations and inscriptions. From the simple painting of the XVIII Dynasty, they passed to the bas relief and to the engraving of the XIX and XX Dynasty. Among the depictions stand out those of the Book of Amduat, the oldest of the guides for the afterlife, and the famous spell of the Weighing of the Heart (or "psychostasia") of the Chapter 125 from the Book of the Dead.

The following period, the *Third Intermediate Period* (1,069–656 BC), saw the coexistence of two centers of power: Tanis and Thebes. The rulers of Tanis erected their stone funeral buildings within the walls of the Temple of Amon, while those of Thebes opened the tombs and profaned mummies. Only a few tombs from this period have been discovered or brought to light; however, thanks to classical authors like Herodotus, we can reconstruct quite comprehensively how they could be. At the beginning of the period, a completely new burial appeared in which the funerary chapel was built inside the temple enclosure. The royal tombs, due to their position and construction technique, moved away from the model of the Old and Middle Kingdom burials and those of the Kings Valley, which was abandoned perhaps because of the continuous looting. The burials of the kings of the XXI and XXII Dynasties arise in the southwestern side of the necropolis of Tanis. Here, in fact, inviolate tombs that still hid the treasure rooms were found. Most of the sarcophagi were usurped to be redeployed by the successors of those who were buried there. Priests and officials of the period favored common and family burials and did not hesitate to occupy the most ancient tombs. The decorations mainly included mythological scenes made directly on the sarcophagi, which were made of wood or *cartonnage*.

The few examples of statues of sovereigns dating back to the period refer to the New Kingdom tradition. Statues that belonged to the rulers of the New Kingdom were reused, and minor modifications were made, or the inscription was changed. In those of new production, instead, following the decrease in iconographic variety and the tendency to simplification, the cube statue with smooth surfaces covered with inscriptions appears. Even the kings of the XXV Dynasty, of Nubian origin, were portrayed according to the canons of the Egyptian tradition by introducing Kushite stylistic elements with a round face with African features on a stocky neck and an athletic build. Iconographic innovations include the double *uraeus* on the forehead, tight-fitting headdress, and amulet shaped like a ram's head as a neck ornament (Fig. 11).

With the end of the Third Intermediate Period, Egypt was dominated by dynasties of foreign origin, Ethiopian, and Saitic, which still

Archaeology of Ancient Egypt, Fig. 10 Funerary complex of Deir el-Bahari: the largest temple is the one erected by Queen Hatshepsut

maintained a policy corresponding to the Egyptian canons, but which soon began to fall apart after the Assyrian conquest. Although the history of Egyptian civilization is generally considered concluded with the Arab conquest, in the seventh century AD, actually already in the Late Period and in the following periods, it will no longer be an Egypt as it was in the past but with values now profoundly modified that will not come never reestablished.

Key Issues and Current Debates

The diversification of the research approach and the improvement of methodologies and technical procedures have changed the goals of Egyptologists. The current interest is no longer the description of individual phenomena but rather to insert them in a precise context of historical, sociological, and anthropological analysis. The DAI has promoted an initiative in which it has undertaken to examine the graves of the pharaohs of the I and II Dynasty of the necropolis of Abydos. The excavations conducted there have brought to light a large quantity of materials, including ceramic vessels bearing brief inscriptions and the names of previously unknown pharaohs. It was thanks to these researches that the so-called Dynasty 0 was identified. The joint activity of the DAI and the University of California of Los Angeles at Dra ‘Abu el-Naga (northern part of the Theban necropolis) has brought to light a rich necropolis dating back to the Second Intermediate Period and the beginning of the New Kingdom. These excavations led to the discovery of a new type of funerary architecture and to the knowledge of burial and cult practices typical of the lower-middle class. The aim of the Egyptologist is also to preserve the artifacts and monuments in a way that does not alter their original state. This is what the archaeologists of the French Institute of

Archaeology of Ancient Egypt, Fig. 11 Example of cube statue

Eastern Archaeology (IFAO) are doing at the Deir el-Medina site. This site, contrary to what one might have expected, thanks to the introduction of new technologies, has returned findings and clues that help us understand the role of this village and its inhabitants, their cult, and their beliefs. In addition to this, the restoration of a part of the village was also carried out which allowed new and interesting results to be obtained, for example, the layout of the domestic environments, and some corrections could be made to the layout of the village designed by the Egyptologists who investigated on the site between the end of the nineteenth century and the first half of the twentieth century.

In 2015, several animal mummies were found in a system of catacombs near the temple of Anubis in Saqqara. According to the researchers, it must have been votive gifts to the gods or idols. The necropolis of Saqqara, not far from the pyramid complex of Giza, was discovered in the nineteenth century, but still today, the researchers continue to dig and to find a lot of information in this site.

Finally, modern Egyptology is not a stagnant science. On the contrary, it continues to evolve along with the new technologies of study. The greatest task of archaeologists is to preserve monuments from the collapse of time and to document those findings which, although already studied, deserve to be reviewed more carefully than has been possible in the past.

Archaeology of Animal Burials

Erica Hill
Department of Social Sciences, University of Alaska Southeast, Juneau, AK, USA

Introduction

Animal burials are features identified at archaeological sites worldwide. Dogs are the most common taxon encountered in excavation; however, archaeologists have discovered the intentional interments of large carnivores, birds, reptiles, amphibians, fish, and even invertebrates, such as molluscs. The earliest animal interments date to the Late Pleistocene in Eurasia. While Pleistocene and Holocene hunter-gatherers tended to bury canids (e.g., Losey et al. 2011), many interments in complex societies are distinguished by scale, elaboration, and species diversity.

Definition

Animal burials or, more generally, animal interments are archaeological features in which a complete or nearly complete nonhuman animal was placed in a prepared pit or otherwise intentionally cached, installed, or deposited. Nonhuman animal burials are distinguished from other types of deposits, such as food or butchery debris, by archaeological context and the extent of skeletal articulation. Remains recovered in proper anatomical order have been termed "articulated" or "associated bone groups," or ABGs, and described as comprising "special" or "structured" deposits (Morris 2011). Many of these ABGs are intentional animal burials.

Key Issues/Current Debates/Future Directions/Examples

Entire animals from all vertebrate taxonomic classes, as well as invertebrates, have been intentionally interred by humans for at least 16,500 years. Animals were buried alone, with artifacts, with conspecifics (members of the same species), and with other species – most commonly humans. Some species were interred in cemeteries or catacombs; others have been found beneath structures, within tombs and pyramid mounds, in caves, and in isolated pits. When buried with humans, animals may represent companions, guides, guards, or mediators. In the absence of humans, animal interments may be sacrificial offerings and foundation deposits or represent the expedient disposal of a carcass or ceremonial "trash."

Documentary and archaeological evidence exist for the burial of beloved pets, mounts, and hunting companions, especially dogs, by the ancient Egyptians, Greeks, Romans, and medieval and post-medieval Europeans. Monkeys, squirrels, parrots, and ravens were also considered pets; some were memorialized with stele, cenotaphs, or place names, such as the faithful hunting dog of the Athenian general Xanthippus. However, in societies without written records, the status of buried animals as "pets" is debatable (see Russell 2012 for a thorough discussion of pets in the past).

Canids (members of the dog family, including foxes, wolves, dingoes, and jackals) have been buried in human graves and by themselves more frequently than any other animal taxon; canid burials have been reported from every continent

except Antarctica and are frequently interpreted as those of pets or companions. One of the earliest examples in the world is the interment of a red fox with a human at an Epipaleolithic site in Jordan. The fox has been interpreted as a companion to the deceased human, sharing a bond significant enough to be memorialized in death (Maher et al. 2011). In the succeeding Natufian period, the number of deceased humans accompanied by animals increases, establishing a global pattern of human-animal burial. Early proposed "pet" burials include that of a puppy with an elderly woman at Eynan, Israel, and a cat in association with a human grave on Cyprus about 9500 years ago.

Evidence from some human burials suggests that the deceased was buried with an animal who embodied membership in a specific clan, kin, or ethnic group. Such practices are associated with societies that recognize human descent from animal ancestors, identified as totems. The totem animal – as an ancestor – may have facilitated transition into the world of the dead by the deceased while simultaneously signaling group membership. Animal interments interpreted as totems, ancestors, or markers of descent include examples from Neolithic Orkney (eagles), Latvia (jay), the Natufian of Israel, and the Ohio Hopewell.

Similar in function to animal ancestors, dogs, horses, and geese may have been placed in human graves to serve as guides or guards after death. In Iceland, the burial of horses with both men and women highlighted their roles in mediation and transport (Loumand 2006). Like the mythic Norse steed Sleipnir, who was able to travel to Hel, these horses ensured safe passage of their human companions into the afterlife. In Iron Age Denmark, the richly furnished graves of warriors sometimes contained entire geese (Gotfredsen 2013). Being noisy and aggressive and with excellent vision, geese were considered superb guards by the Romans, who associated them with the god Mars. Burying geese commemorated the vocation of the deceased while protecting him on his postmortem journey.

Not all animals buried with humans were companions, pets, or guides, however. Some animals were interred in ceramic vessels, placed on plates, or found in association with food and drink. These animals appear to be grave gifts or food offerings intended for the deceased. In agricultural societies, domesticates were commonly interred with the dead as food for the afterlife. While entire animals were sometimes deposited this way, more frequently, only animal parts, such as the head or a joint of meat, were included in inhumations. The remainder of the animal was likely consumed by mourners at funerary feasts.

Interpretations of animal interments independent of human remains include votive or foundation deposits, expedient discard of a carcass, and disposal as ceremonial "trash." In contrast to food offerings for the deceased, these burials were often sacrificial, intended to give thanks, commemorate or memorialize a person or event, or obtain blessings or benefits from spirits, ancestors, or deities. For example, deposits of millions of mummified cats, dogs, and ibises in the Egyptian Late Period likely represent votive offerings made by pilgrims. Each animal was associated with a specific deity in the Egyptian pantheon. The purchase and interment of an animal mummy thus honored the god and conveyed the human worshipper's request for a blessing or good fortune (Ikram 2005). Among the ancient Maya of Mesoamerica, offerings may have functioned in a similar way; votive animals may have been selected to appeal to specific deities or mythic figures. Catfish offerings placed in graves, for example, may have garnered favor from the Hero Twins, who had once taken the form of catfish.

Foundation deposits are a specific kind of votive feature found in association with architecture, including temples, pyramids, bridges, walls, dams, and granaries. These interments mark the initiation of a construction and are intended to consecrate it and protect its contents or human inhabitants. Entire horses, cattle, sheep, and deer have been recovered from beneath medieval structures throughout Europe. Even more common was the deposit of skulls or jawbones of domesticated animals. The ritual use of such animal parts has considerable time depth.

Among the best known examples are the bucrania of bulls and rams from the site of Çatalhöyük. Beginning some 8000 years ago, inhabitants of this Anatolian site installed the skulls and horns of bovids in rows on benches and walls. The use of domesticates, especially bovids (sheep, goats, cattle), signals a major change in human-animal relations, as people in many parts of the world shifted from a foraging economy to one dependent upon animal husbandry and agriculture.

Analogous to foundation deposits, animal burials may also mark the ritual closure of buildings. Such features occur within existing architecture, rather than beneath its foundations, thereby ending the use-life of the structure. One example is the interment of dogs in the center of kivas, circular ritual structures common at sites in the Southwestern United States. In the Bronze Age Near East, donkeys served a similar function; they have been found in fill atop temple complexes.

Some animal burials represent "ceremonial trash" or the expedient disposal of carcasses. One of many interpretations of the 1000+ dogs interred at the site of Ashkelon in the Levant is that they were respectfully discarded after their use in healing rites (Edrey 2008). A similar explanation has been proposed for the mummified guinea pigs buried at the site of Lo Demás, Peru. Some of these "ritual rodents" may have been used for divinatory purposes, as well as in healing rites (Sandweiss and Wing 1997). Such animals could not be discarded like household trash; instead, they were deliberately interred at sites that resemble animal cemeteries. Social proscriptions also structured Roman disposal of horses and dogs at frontier military sites. Considered animal "comrades," neither horses nor dogs could be eaten. Their bodies may have been deposited expediently and fully articulated but without deliberate burial or grave goods.

Other possible interpretations of animal interments without accompanying human remains include burial of the animal as a person, an intentional social agent, rather than as a votive object or offering. Like some humans, some animals appear to have been the focus of mortuary ritual, meriting special treatment that distinguished them from conspecifics and paralleled the treatment of human dead. For example, in 2300 BCE, an Egyptian hound named Abutiyuw was buried at Giza with an inscription reading: "His Majesty ordered that he [the dog named Abutiyuw] be buried [ceremonially], that he be given a coffin from the royal treasury, fine linen in great quantity and incense. His Majesty also gave perfumed ointment and ordered that a tomb be built for him. . .. His Majesty did this for him that he [the dog] might be honoured before the great god Anubis" (Reisner 1936: 97).

The inscription about Abutiyuw focuses attention on a particular animal's experience of life and death, inviting a biographical approach to animal burial. Notable examples include Losey et al.'s (2011) osteobiographies of two canids interred in a Siberian cemetery and Argent's (2010) study of horse burial at the Iron Age site of Pazyryk. These studies suggest that humans recognized the unique characteristics and personalities of specific animals and commemorated those features in burial. A similar approach was taken by Campbell (2014), who sought to reconstruct the experiences of particular animals in his exploration of the social entanglements and life histories of a chariot horse, a dog, and a deer at the site of Anyang, China. He traced the "pathways" of each animal through training, hunting, sacrificing, consuming, and interment.

The innovative works of Losey, Argent, and Campbell recognize the subjectivity of animals, highlighting the fact that, like humans, animals are agents who experience their own lives and are capable of deliberate action. Certain animals, like certain humans, were persons. An even smaller fraction, however, were set apart as the incarnations of gods or ancestors. Catacombs at the site of Saqqara, Egypt, contained massive sarcophagi and mummified remains of Apis bulls, each of whom was believed to embody the god Ptah. The bodies of these animals were interred in ways that paralleled Egyptian treatment of elite humans, suggesting that the personhood and divinity of each bull was recognized and memorialized in death. Perri et al. (2015) have suggested a similar interpretation for the burial of a bobcat from a Hopewell site in Illinois; the animal wore a

collar of shell beads and bear teeth and was interred in a mound near several humans.

In contrast to the biographical or life history approach to animal interments, archaeologists in Mesoamerica have recently suggested that elites and ritual specialists used animal bodies in public ceremonies and as demonstrations of power. Display and burial of exotic, nonnative animals could be spectacular and performative, intended to showcase territorial conquest, as at the Aztec Templo Mayor at Tenochtitlan (López Luján et al. 2014). Animal burial could also make powerful statements about social hierarchies and inequalities. At Teotihuacan, powerful carnivores such as eagles and jaguars were captured, caged, and buried. Like human sacrifice, the ritual interment of these animals demonstrated the control of the state over inhabitants both human and nonhuman (Sugiyama et al. 2014). Royal menageries – for example, at the Tower of London – fulfilled similar roles by showcasing the power of a ruler through the physical restraint and subordination of exotic animals such as lions and elephants. The burial or disposal of their bodies therefore provides archaeological evidence of the use of animals as symbols and spectacles.

This essay has outlined some of the archaeological patterns in animal burial, focusing on deposits in which entire, or almost entire, articulated animals are found in intentional features. When animals are identified in burial contexts with humans, they tend to be interpreted as companions, pets, or guides to the afterlife. Some may embody descent group membership as totems or ancestors. However, when only animal parts are found, archaeologists generally assume they are food offerings or otherwise meant to serve or assist humans in the world after death.

Nonhuman animals were also interred without humans, with artifacts, members of their own species, and with other species. These interments are generally interpreted as foundation deposits and votive offerings to a deity, or they represent ceremonial "trash" or expedient disposal of a carcass. Recently, some archaeologists have suggested that certain animals were recognized and treated as agential persons. A life history approach to animal burial prioritizes the acts and experiences of animals as individuals, challenging anthropocentric reconstructions of the past.

To understand animal interments, archaeologists must situate them within the broader context of a society's foodways, beliefs, and rituals. Mythological or religious associations of animals with deities, culture heroes, or ancestors have been productive avenues of research. Archaeological context of the burial or deposit is also critical, including extent of articulation, disposition of the skeleton, and evidence of trauma. Like humans, animals had complex social roles in past societies as companions, guides, guards, sacrifices, offerings, the embodiments of gods and ancestors, and persons in their own right. They interacted not only with their human cohabitants and conspecifics but also with members of other species. Context-sensitive approaches to animal interment that consider such factors promise to yield more nuanced (pre)histories of the human-animal past.

Archaeology of Art: Theoretical Frameworks

Dánae Fiore
CONICET-AIA-UBA, Buenos Aires, Argentina

Introduction and Definition

This entry provides an overview of the main *theoretical frameworks* used in the *archaeology of art* and outlines their main contributions and limitations. These frameworks can be defined as sets of *concepts* used by researchers to approach the *analysis and interpretation* of *visual imagery* in the *archaeological record*, which includes *materials* such as rock art (petroglyphs, paintings, and geoglyphs), portable art (decorated tools and artifacts with no practical-mechanical function), sculptures, friezes, body ornaments (beads, pendants, etc.), and pottery decoration. These theoretical frameworks have varied along the history of archaeology according to factors such as the following: (a) *ontology*, the way "art" is defined and conceived from each specific theoretical perspective; (b) *epistemology*, the way art analysis and/or interpretation is carried out, that is, whether it uses induction and/or deduction, whether it focuses on qualitative descriptions and/or searches for quantitative patterns, and whether it uses one or more lines of independent evidence (e.g., image data, technical data, spatial data, archaeofaunal data, and ethnographic data); (c) the *topics* which are central to each framework and which are reflected by the *questions* asked about the materials under study and by the *concepts* used to describe, explain, and interpret them; and (d) *methodology*, the practical ways in which *data* are collected and *variables* are measured in the field, analyzed in the laboratory, and presented within the academic community (theoretical frameworks have also varied according to their historical and sociocultural contexts, but these will not be addressed here due to space limitations).

Some theoretical approaches to art stem from wider archaeological theoretical frameworks (e.g., culture-history, processual, post-processual, and evolutionary-ecological; see below), and thus, their concepts are mainly applications of their particular conceptions about past human cultures to the analysis and interpretation of artistic materials in the archaeological record. Other approaches derive from the application of theoretical frameworks generated in other disciplines than archaeology, such as anthropology, linguistics, or sociology (e.g., structuralism, semiotics, and historical materialism; see below). Finally, others focus particularly on the development of hypotheses about art's functions (e.g., shamanism and art as landmarks along caravan routes; see below) which have been developed to tackle specific cases-studies (Fig. 1).

Historical Background

Foundational Approaches: The Pioneer Interpretations

In the late nineteenth century, researchers followed evolutionist ideas that viewed prehistoric hunter-gatherers as "savages" with a minimal cultural development; hence, they did not conceive that they could have the creativity potential to produce art. This was reversed by series of archaeological discoveries, firstly of portable art in Paleolithic contexts (e.g., Lartet and Christy 1865 in Ucko and Rosenfeld 1967; Bahn and Vertut 1988; White 2003) and later of rock art of Paleolithic origin (see De Sautuola-Carthailhac debate in idem). Interestingly, by that time similar findings and inferences about art's antiquity were also being made in other continents: in South

Archaeology of Art: Theoretical Frameworks, Fig. 1 Theoretical frameworks in the archaeology of art

America, some of the first rock art discoveries were made as early as 1876 in Patagonia (Argentina; Moreno 1876) and in 1877 in Northwest Argentina (Liberani and Hernández 1950), and in both cases, they were attributed to native peoples of pre-Hispanic times (which are obviously not comparable to Paleolithic antiquity but are conceptually comparable insofar as they are both prehistoric contexts).

As part of the realization that art had prehistoric origins, the first interpretations about its origins and purposes were proposed. Given that by that time archaeology was still not a formal academic discipline, these hypotheses were not developed within an explicit archaeological theoretical framework but rather were ideas that stemmed from the contemporary conceptions about Paleolithic life, about Western art, as well as from ethnographic analogies with hunter-gatherer societies living in several territories colonized by European countries.

An early interpretation, known as "*art for art's sake*," proposed that *portable art* had *no meaning*, pursued only an *ornamental* purpose, and was produced due to plentiful Paleolithic environmental conditions which enabled hunter-gatherers to dedicate to these activities during their spare time (Lartet and Christy 1864 in Ucko and Rosenfeld). Interestingly, this idea is detectable in contemporary authors of South America: for example, when referring to rock art from Patagonia (Argentina), Burmeister (1892) inferred that these images had been made by the native inhabitants during "leisure times." This hypothesis is difficult to test insofar as meaning is the most evasive aspect of prehistoric art. However, the fact that visual patterns are sometimes repeated within individual items and among assemblages indicates an intentional reproduction of certain decorative motifs which can be interpreted as socially significant, that is, responding to cultural norms of material culture design, presentation, and use, regardless of their potential symbolic meaning. Moreover, it is also interesting to note that the *emphasis* placed by Lartet and Christy on *environmental conditions* entails that already this early hypothesis was taking into account a *production context*, which, in turn, was positively valued in spite of the dominant negative ideas about hunter-gatherer life.

A second pioneering interpretation was that of *totemism*, which originated in *ethnographic analogies* and asserted that some Paleolithic *rock art motifs* could be conceived as *symbolic representations* of *kinship ancestors* (Reinach 1903). Such hypothesis, which had relatively little academic impact, only took into account few animal representations and disregarded other motifs and was clearly very hard to test. However, it did bring into attention the fact that prehistoric art could have had a social function, in this case related to identity and ritual use.

A third interpretation was that Paleolithic art had been produced as part of *sympathetic magic* rituals carried out in order to increase success in *hunting prey* and/or in its *fertility* and thus in its availability for further hunting (Reinach 1903; Breuil 1952; see details in Ucko and Rosenfeld 1967; Bahn and Vertut 1988; White 2003). This interpretation was based on the fact that *species* represented in rock art were also *consumed* by Paleolithic people, as well as the fact that the images' *location* was often hidden in *dark panels* of caves, a context that was assumed as likely for *ritual practices* and not general domestic use. Superimposed motifs were interpreted as ritual reiterations, while marks made on rock art and clay-modeled animal representations were interpreted as symbolic wounds. In turn, rock art depictions of animals with swollen abdomens were seen as pregnant individuals, while the portable "Venus" figurines were considered as fertility symbols given the exaggeration of the reproductive portions of the human female body in some of these figurines.

The number of images interpreted via this approach was later expanded by Breuil (1952) to account for other motifs: for example, predators which were not part of the diet were depicted to control them symbolically; geometric signs were representations of traps or weapons; incomplete animals were represented as deprived of their senses or body parts in order to symbolically prevent them from escaping; human hands

superimposed or near to animal figures represented their appropriation.

Criticisms to the sympathetic magic hypothesis have been many, including the following: (a) hunting scenes are infrequent, (b) some animals with swollen abdomens are male, (c) most represented animals are not "wounded," and (d) there are discrepancies between the represented taxa in the archaeofaunal and artistic records (a point that would later be approached by other frameworks; see below). Moreover, the exclusively inductive epistemology underlying these interpretations also weakens their explanatory power. However, one of its core contributions is the combination of an idealist ontology with some materialist underpinnings: the symbolic aspects of art are combined with its core practical functions in a hunter-gatherer world where prey availability seems crucial. Furthermore, both Reinach and Begouen (in Ucko and Rosenfeld 1967) stressed the fact that the *act of making* these images was essential to the *performance* of the sympathetic magic rites, a detail which points to an early – though implicit – interest in what later would be the concepts of praxis and engagement through art production.

Normative Approaches: Culture-History and Structuralism

Normative approaches to the study of art in archaeology share in common the fact that they consider *culture* as a *set of shared norms*; hence, art materials would reflect such norms in their design and technique.

Culture-history was the first formal theoretical framework developed in academic archaeology by authors such as Willey and Phillips. It operated within a normative conception of culture, and its main aim was to identify "*archaeological cultures*" or "*industries*" defined by spatial-temporal distributions of artifact *types*. Each type was defined by one or more trait/s that allowed the *typological classification* of artifacts found in the archaeological record. In turn, archaeological cultures involved specific artistic *styles*, defined by similarities in the types of motifs (their form, color, etc.), their layout on the artifacts, the themes represented in the figurative images, the techniques with which they were created, etc. Culture-history analyses tended to create *periods* which organized the archaeological cultures in a diachronic succession: thus, when approaching art, this theoretical framework created *stylistic sequences*. With portable art, these were mainly based on the stratigraphic position of decorated artifacts in successive layers of sites. In rock art these were based on (a) the superimposition of images, which were used as indicators of their relative dates, and (b) the indirect association of rock art images located in the walls of a site with pigment residues in sequential archaeological layers, dated sediments sealing the walls, or fallen wall fragments with imagery buried by the sediments.

These stylistic sequences were related by the authors to the periods not only as a way of providing a context to the former but also as a way of defining the latter. Yet it is interesting to note that in several cases there was no univocal correspondence between one style and one archaeological culture, implying that despite of the "shared cultural norms" premise, archaeologists did not assume that industries and artistic styles changed necessarily in a coordinated manner. For example, in Western European Paleolithic art, Breuil (1952) defined two "cycles," Aurignacian-Perigordian and Solutrean-Magdalenian, while similar – though more complex – stylistic sequences were proposed by Laming-Emperaire and Leroi-Gourhan. This kind of stylistic scheme was applied to the study of portable art and rock art in many other regions of the planet (e.g., Gradin et al. 1979 in Patagonia, Argentina).

Due to its emphasis on culture as a set of shared norms, this framework focused mostly on the types of artifacts and of motifs which could be used as "fossil guides" due to their high frequencies and/or visual distinctiveness, to construct cultural periods and stylistic sequences, thus disregarding cultural variability. Its idealist ontology – entailed by the notion that culture was a "projection" from mind to practice – and its highly inductive epistemology also limited its explanatory power insofar as little room was left to move

beyond descriptive and empiricist accounts of the past. However, the creation of art periods and stylistic sequences is still used by most archaeologists as a means of organizing archaeological data, although it has now become clear that this is only a means, and not an end, in the archaeology of art.

A second and entirely different normative approach to art was *structuralism*. In accordance with the core ideas of Levi Strauss about culture being structured by associations and oppositions as a reflection of the human mental structure, and following early suggestions by Raphael in 1946 about the fact that in European Paleolithic rock art animal representations were spatially displayed with a nonrandom structure, Leroi-Gourhan (1964) and Laming-Emperaire developed systematic analyses in search for spatial patterning of motifs in European cave art. Such analyses were carried out by (a) *classifying motifs* in *groups* (e.g., A = horses, B = bovines, P = fish, a = lines and dots signs, b = ovals and triangles), (b) partitioning the *topographic zones* of the caves (e.g., entrance; central zone; passageway; etc.), and (c) *quantifying* the motif groups in order to search for their *combination patterns* and their *links* to the *topographic zones* (Leroi-Gourhan 1964). The emerging patterns were then interpreted as *mythograms*, that is, the graphic symbolization of shared myths whose structure was projected from the mind to the cave walls. Such structure emerged from *dual associations and oppositions* such as light-darkness and life-death. Also, certain *animal motif types* were also associated to certain *geometric signs* and attributed a *sexual meaning*.

Although these authors also developed stylistic sequences in the normative fashion with an essentialist and idealist ontology, the differences of structuralism compared with the former framework are profound: (a) its emphasis on a synchronic view of art, (b) its partially inductive and partially deductive epistemology, (c) its use of quantitative data, and (d) its highly interpretive approach to the emerging patterns. Criticism did focus precisely on these issues: for example, the synchronic view collapsed images made centuries apart into one single data corpus and the mythogram interpretations were untestable. However, this framework did develop for the first time the systematic recording and quantification of art data (motif types, their combinations, and their spatial location) and proposed a testable hypothesis regarding the nonrandom layout of images, which are still of relevance in the archaeology of art.

Processual Approaches: Variability, Adaptation, and Information Exchange

A revolutionary breakthrough from normative theories was achieved by a group of archaeologists in the 1960s (e.g., Binford, Flannery, Schiffer, Redman, Renfrew, Watson, Wobst, etc.) who, following ecological concepts applied to the study of human behavior, proposed a definition of *culture* as an *extrasomatic means of adaptation* of *people* to the *environment*. This meant that culture could be seen as a *system* integrated by several *subsystems* (subsistence, technology, etc.), each of which complied with a specific *function* in the adaptation of a human group via the deployment of *adaptive strategies*. Thus, breaking away from finding cultural norms and creating periods which focused on the average items of the archaeological record, these "new archaeologists" focused instead on the study of cultural *variability* and on the circulation of *materials*, *energy, and information* along wide spatial scales. This materialist ontology was combined with a hypothetico-deductive epistemology: both were foundational in one of the most innovative and pervasive archaeological frameworks (though with obvious shortcomings; see below).

Although its main concern was with subsistence and technology, this theoretical framework had a clear impact on art analyses. Archaeologists following this perspective stressed the need to (a) study variability *within* broad periods such as "Paleolithic art" which covered thousands of years and often masked actual variations in human behavior, (b) consider that terms such as "parietal art" or "portable art" were also labels that often masked variability in spite of their

usefulness in academic communication, (c) go beyond inductive typological descriptions of periods and stylistic sequences and offer explanations proposed by explicit hypotheses tested against systematically analyzed data, and (d) focus not just on the potential symbolic meanings of art (which are often unattainable) but also on art's functions within the human groups that produced it (e.g., Conkey 1985).

These ideas were applied to several Paleolithic case studies, in which authors – following Wobst's demographic simulations and analyses about hunter-gatherer populations – focused on portable art and/or rock art similarities to identify inter-site links viewed as evidence of regional interaction. Art was a key evidence through which networks, alliances, and aggregation sites were identified by (a) qualitative comparisons between *designs* (Bahn 1982; Gamble 1982), (b) inter-site comparisons of relative *frequencies* of *decorated artifacts* (Conkey 1980; Bahn 1982; White 1992), (c) detailed analyses of *element repertoire* and *structural principles frequencies and diversity* (Conkey 1980), and (d) *number* of rock art *sites versus* stylistic *regionalization or homogeneity* (Jochim 1983). These data were contextualized by their environmental setting (e.g., paleotemperature, sites' geographic location, vegetation distribution, faunal diversity, carrying capacity, exploitation and intensification strategies, and their relation to the relative population densities they could afford) to characterize the natural and social context in which these "adaptive strategies" were operating.

In accordance with the processual agenda, these studies tended to see art production and use as a means of overcoming environmental stress and potential competition for resources triggered by environmental changes and/or demographic pressure by creating and reinforcing social bonds. This functionalist view of the adaptive purposes of art has been subsequently criticized by several authors (including self-criticism by some pioneers of this framework; e.g., Conkey 1984) for its environmental reductionism and for its teleological reasoning. While taphonomy/conservation, sampling, identification, and publication were explicitly considered as biasing factors of the artistic materials within the archaeological record (e.g., Bahn 1982; Conkey 1985), these analyses have been criticized because of their sampling strategies and statistical methods, which have subsequently been refined.

Following the adaptive approaches to culture, *style* and *function* were dichotomically conceived by some authors, the latter being considered as adaptive while the former being considered as nonadaptive (e.g., Dunnell). However, other authors argued that style did have specific adaptive functions as *systems of information exchange* (e.g., Wobst). This, in turn, led to a whole debate on the active and passive functions of style which are applicable to art analyses (see the entry on "► Style: Its Role in the Archaeology of Art" in this encyclopedia).

Another crucial development within this framework was the flow model presented by Schiffer in 1972 "to view the" life history "or processes of *systemic context* of any material element" which included "procurement, manufacture, use, maintenance, and discard," in order to account "for the production of a substantial portion of the *archaeological record*." This model, similar to the *chaîne opératoire* concept, was adapted to the analysis of rock art production by Aschero (1988) and applied to the study of production sequences of portable art by White (1992); clearly, both models supercede the processual agenda and are useful for the study of art materials from other theoretical perspectives.

The main criticisms to this theoretical framework were (a) its ecological reductionism and determinism, which often is not enough to explain art's creation, uses, and changes; (b) its teleological conception of culture, and art within it, as exclusively a means of adaptation, which leaves aside other potentially "nonadaptive" uses of art; and (c) its functionalist view of culture, and art within it, as a homeostatic system which paid little attention to its potential internal contradictions, which are often core factors leading to change. Although the search for variability was a key contribution of processualism, which is part of the research agenda nowadays, paradoxically its deterministic view sometimes gave little room to

the study of the diversity of human actions, that is, human agency, social divisions, and inequalities. Other theoretical frameworks took up these challenges.

Post-processual Approaches: Symbolism and Interpretation

One of the strongest reactions to the processual framework in the 1980s can be found in publications by, among others, Bender, Conkey, Hodder, Shanks, and Tilley who criticized it as positivist, reductionist, functionalist, and deterministic. Following post-modern concepts, they proposed instead that archaeologists cannot reach an objective truth about the past because the *past* is a *construct* made from the *present*, and as such it is a *situated* and *subjective* construction – that is, biased by the socioeconomic status of the researcher, his/her cultural and ideological background, and his/her gender, values, intentions, etc. Thus, the key means to approaching the archaeological record was via its *interpretation*, metaphorically reading it as a text, and offering as a result not necessarily just one but several subjective and *multivocal* insights to the past. Against the processual view of human behavior as a passive response to environmental conditions, post-processual archaeologists saw *human agency* as an active construction of *subjective relationships* between *persons*, *objects*, and *landscapes*. Thus, *material culture*, including art, was conceived both as *active* (bearing traces of its producers' actions but in turn having further effects on its users' actions) and *meaningful* (bearing multiple – sometimes ambiguous – senses and intentions). This was partly derived from ethnoarchaeological observations such as those made by Hodder, who studied the *decoration* of calabashes in the Ilchamus society of Kenya and inferred that, in this male-dominated society, these objects were decorated by women with designs that had several meanings, some of which were *gender*-related and *symbolized* female resistance.

A foundational example of the application of this framework to rock art interpretation is that of Tilley (1991), whom in his study of the engraved "*de*signs" of Nämforsen (Sweden) developed the following themes:

(a) An initial question about "What is their meaning, significance, and value**today**? . . . Or can we hope to mediate them productively, reinscribe them into the present, and open out the carvings to subjective experience once more?" (Tilley 1991: 8).
(b) Several interpretations of the carvings' meanings, including the use of the petroglyphs as totemic symbols (expressed through nature/culture dual oppositions), as ideological reinforcements of social control between the hunter-fisher-gatherer groups and as intragroup symbols operating in terms of age and gender distinctions (idem: 99, 167, etc.).
(c) An open dialogue with the reader in which he portrays the critical questions he thinks the reader will ask of his book, for example, that the discourse includes an open-ended array of possibilities, that the author has evaded his responsibility to tell the reader what the carvings in fact mean, and that the author's relativism destroys any productive links between past and present. To this, he replies that a "totalizing framework" or "totalitarian solution" that tries to box in many interpretations will anyway leave a surplus of meaning/s that cannot be captured in one single discourse (Tilley 1991: 173). Through such final deconstruction of his own work, the author actively engages the reader in the realization that unique conclusions are neither feasible nor desirable in the human sciences.

Other post-processual conceptions and analyses of art have been less relativist and skeptical and have focused on applying concepts related to art's spatial distribution, such as the notion of social geometry, with lattices of people and objects deployed in space to *construct socially meaningful landscapes* (Conkey 1984). This includes the knowledge to navigate in these landscapes, which is not just verbal but also expressed through material culture (e.g., movable, as in portable art, and fixed in space, as in rock art). Thus, following Bourdieu's notion of habitus, Conkey proposed that human practices and knowledges structure space and in turn such structured space structures humans: the reproduction of such

trends can be identified in the archaeological record (idem). This kind of approach to the ways in which people have engaged themselves in the construction of a visually marked landscape via rock art placement at significant locations has been fruitful and is still used nowadays (Bradley et al. 1994).

Finally, the interpretation of art from the *aesthetics* point of view – defined as the particular way in which a person experiences an object and through such process generates a subjective feeling – can also be included within the broad spectrum of post-processual approaches to past visual imagery (see the entry on "▶ Aesthetics in Archaeology" in this encyclopedia).

This framework has pinpointed a crucial issue in terms of the *self-awareness* and *self-criticism* that archaeologists need to develop by acknowledging the *biases* of their *situated knowledge-construction process*. However, in spite of such contextual approach, the idealist ontology and the hermeneutical epistemology of post-processual framework can be criticized for their extreme relativism, which leads to the notion that any interpretation is valid. Moreover, post-processual discourse can end up being more self-referential (about the researcher) than analytical and informative about the persons who lived in the past: if multi-vocality is truly advocated, then those *past voices* and *agencies*, which are inscribed in the *materiality* of archaeological *artefacts-images*, should also be listened to, without of course claiming that they can be accessed objectively. Thus, it is useful to draw a distinction between the *past events* and the *knowledge about the past*: present researchers have had no intervention in the creation of the former but do have total intervention – and responsibility – in the construction of the latter.

Social Approaches: Ideology, Power, and Economy

Partly independently and partly as a response to processualism, a relatively small group of archaeologists started applying *materialist* and *neo-Marxist* concepts to archaeological analysis (e.g., see publications by Bate, Earle, Gándara, Lumbreras, McGuire, Patterson, Vargas Arenas, etc., which in some cases follow the much earlier and foundational work of Childe). Challenging processualism, this framework pointed out the fact that culture is not always a means of adaptation due to several reasons, including that *societies* are often *not homogenous*, hence not all members of a group have the same chances of accessing *resources* and *information* vital for their social reproduction: culture can adapt some people at the expense of not adapting others. From this point of view, the basis of a society is its *economic structure* (briefly defined as the division of labor entailed in the process of extraction-production-circulation-consumption of raw materials, finished goods and services, the property of production means and of their profits). This determines the existence of a *political and ideological superstructure* developed to sustain and *reproduce* such structure, particularly when it entails situations of *social inequality* and *labor exploitation*. Within this framework, *art* has mainly been considered as part of *political strategies* manipulated to maintain control and enforce *power*, as well as part of *ideological discourses* to *mask* and/or *justify inequalities* (Earle 1989; Lumbreras 1998; Pérez Gollán 2000).

Such *political functions* to create and reproduce intragroup differences can be identified by studying art styles and luxury items, which are a means of conferring and sustaining *status* and *power* due to the fact that they operate visually, catching people's attentions and generating aesthetic reactions – which are sometimes difficult to manage rationally, hence their high effectiveness (Earle 1989). Moreover, the power emanating from durable objects tends to feel more permanent, hence unquestionable, thus conferring solidity also to the social position of their owners (Earle 1989). In turn, *ideological functions* of art have been often studied by analyzing the images' motifs/topics and the ways in which these are represented: for example, in the case of Aguada style (found in the pottery, metal objects, wooden artifacts and textiles from Northwest Argentina), the images of a sacrificer holding a human head and, particularly, of a feline are pervasive throughout these materials and have been interpreted as a means of *legitimizing* power and hereditary social

inequality, by linking the governants with sacred beings and, through such iconographic manipulation, represent the elites with divine attributes (Pérez Gollán 2000).

These analyses of the political and ideological functions of art have focused heavily on art's capacity to express ideas and thus on the *mental dimension* underlying its creation and use, while the *material conditions* in which it was produced and displayed have mainly been considered as an *external context* which determined art creation, but have often not been thoroughly analyzed as an *internal component of art's production*. However, some authors have indeed noted that art can also be conceived not just as a *representation* but as a *presentation* of a material object and, as such, as a "*productive work*" (Lumbreras 1998). Thus, the artistic *work process* can be reconstructed via the analysis of the *production sequence* (Aschero 1988; White 1992). Also, conceiving *art* as an *economic product* entails that it is a material artifact made through the combination of *productive forces* (raw materials, tools, techniques, human labor) and *social relations of production* (the engagement of persons and materials and knowledge in such work process) in order to create an image-artifact. In turn, art production entails a certain *labor investment*, which can be assessed via multiple variables, for example, (a) media on which to produce the images, their abundance/scarcity, accessibility/inaccessibility, hardness, and texture; (b) raw material availability to make tools and prepare paint; (c) expedient/curated nature of engraving and painting tools; and (d) simplicity/complexity of image-making techniques and of visual designs produced with them. The study of such variables allows one to transcend a descriptive approach to the *materiality of art* and is relevant to characterizing the amount and quality of labor invested in its production, thus revealing economic aspects underlying its creation, which in turn shed light on some of the ways people *engaged* themselves – through practical manipulation and visual perception – with the *material features* of these images.

The orthodoxy of these approaches has been rightly criticized for its reductionist economic determinism and for its mechanistic and teleological approaches to art's functions as mere reproductive reflections of the economic structure. Moreover, on many occasions, the potential political and/or ideological functions of art are not well grounded, hence reducing the explanatory power of these concepts. For this reason, materialist and neo-Marxist approaches need to not just assert but demonstrate in each case why and how a certain art form has complied (or not) with such functions. Yet, breaking away from the Cartesian mind-body split, which originally led to art being associated with ideology and not with economy, and recognizing that art is *intrinsically* and *simultaneously* ideological-political-economic, strengthens the viewpoints proposed by this framework. Moreover, its materialist ontology – which allows to focus on contextual *and* internal material aspects of art production and display – and its dialectical epistemology, combining deduction and induction, have great potential within the archaeology of art.

Approaches to Art as Visual Communication: Semiotics, Cognition, and Expressive Symbolism

Most frameworks do involve the notion that art has a communicative aspect, but two frameworks have focused on this feature as their core concept. On the one hand, following the work of linguists and semioticians such as Saussure, Peirce, and Barthes and also having clear influences from the structuralist framework presented above, the *semiotics* approach has put forward the notion that visual art is the product of an act of *communication*, which includes a *source* who produces a *message* containing information, a *code* in which it is formulated, a *channel* through which it is transmitted, and *receiver*(s) who decodes it (if they share a common code with the source) and who may respond or *feedback* to it. Three sets of rules function in the code in order for the information contained in the message to be transmitted: *syntactic*, *pragmatic*, and *semantic*. The first two have clearly a greater chance of archaeological visibility in art designs, since the *types* of motifs and their *spatial relations* in terms of association, juxtaposition, direction, distribution, etc. (e.g., Llamazares 1992) can help identify

aspects of the rules underlying the syntactic composition and pragmatic use of the images.

Also having developed partly from structuralism, approaches oriented to the study of *cognition* in the archaeology of art have focused on analyzing the steps taken by past artists in the creation of images with specific features (symmetry, size, etc.) and how their *visual perception* has participated in such process. To do so, special attention has been given to how *forms* (a) are *selected* and filtered among a wider array of possibilities, through the emphasis of some details and the omission of others, in order to facilitate and *economize* their visual perception and interpretation; (b) are *categorized* within each cultural context; and (c) are contained within a *cultural memory* which allows the *organization* of image perception, makes images *recognizable* and *significative*, and influences the *elaboration of future forms* (Washburn 1983). Finally, following Parsons' work, the *expressive symbolism* approach has proposed that an art object functions as an expressive symbol when it operates as a token of the *feelings* or the *attitude* of an "ego" toward an "alter," thus mediating the *affective component* in such *interaction* (Tanner 1992).

The complete application of these approaches seems to require other sources of information rather than just the archaeological materials, thus being more fully applicable to historic than to prehistoric cases. Yet many approaches developed by these frameworks can be found in diverse case studies.

Approaches to Art's Functions: Case-Oriented Hypotheses

A number of art analyses are based not on wide theoretical frameworks but rather on specific hypotheses which are oriented and applicable to specific case studies. Such is the case with *Shamanism*, which proposes that many rock art motifs are representations of images seen during *altered states of consciousness*, induced through *trance* and/or through the consumption of *hallucinogenic substances* which generate *entopic phenomena* (Lewis Williams and Dowson 1988). The application of this hypothesis, originally developed for South African cases, requires the use of ethnographic information as an independent source of data to corroborate it when applying it to other case studies in order to avoid equifinality problems: otherwise, similar motifs could be ascribed to shamanism when in fact they may well be the product of rather different causes.

Another function attributed to rock art is that of marking significant points and roads along *caravan routes*. This hypothesis has been tested by plotting the distribution of rock art sites and motifs depicting llama herds along wide spatial ranges in Northern Chile and checking their correspondence with trails followed by llama shepherds on their travels across long-scale distances and with sites containing evidence of these faunal resources (Nuñez Atencio 1976).

Rock art has also been related to *identity* in two different and complementary manners: (a) as an *archaeological indicator* of social groups and their boundaries and (b) as an *intentional* construction of *self-expression* of social identity (Domingo et al. 2008). What they share in common is that identity is a twofold phenomenon, which requires simultaneously the construction of *similarities* to produce a *sense of belonging* to a group and of *differences* to *distance* such group from other surrounding groups. Thus, identity may have archaeological visibility, although it is sometimes difficult to distinguish whether such identity is mainly a construction by the archaeologist derived from a set of visual designs attached to material culture or whether such designs were intentionally produced as an identity expression. In turn, this notion is very much related to that of style (see above and also the entry on "► Style: Its Role in the Archaeology of Art" in this encyclopedia).

Finally, the sets of marks such as dots and notches found on the surface of many Paleolithic portable art items have been interpreted as *notation systems* (e.g., lunar calendars and event tallies). This hypothesis was originally proposed by Marshack (1972) who used *microscopic observations* of *archaeological materials* to provide evidence to support it. However, such interpretations and methods were challenged by D'Errico

(1995) who pinpointed the need to use *independent criteria* derived from microscopic observations of *experimental marks* as *parameters* to assess the observations of the archaeological materials and to recognize whether the sets of marks had been made with a single tool or with several tools and in turn whether it had been made in a single event or along different events (D'Errico 1995; see also White 1992). Heated debate led to the refinement of these methods and to the conclusion that indeed several Paleolithic materials functioned as notation systems, but not all marked artifacts can be interpreted as such.

Evolutionary-Ecological Approaches: Human Behavior, Cultural Transmission, and Natural Selection

Following neoevolutionary concepts but breaking away from the processualist teleological and functionalist explanations about culture, the *evolutionary-ecological* approaches in archaeology led by authors such as Dunnell, Gamble, Lyman, Mithen, O'Brien, Shennan, etc., focused not just on adaptation but on the broader process of how *human behavior* is developed and reproduced within an *ecological context*, thus including *mechanisms* of *variability production*, *cultural transmission*, and their *natural selection* under specific *environmental conditions*. Its materialist ontology and positivist epistemology are also shared with processualism, but the evolutionary framework has entailed a broader spectrum of behavioral possibilities that range from *adaptive* to *nonadaptive* outcomes, thus allowing for a conception of *culture* which is *not always homeostatic*.

Although the core lines of research followed by this theoretical framework do not include art, when applied to the study of such materials, this approach has proposed, for example, that *Paleolithic art* has been regarded as "an emergent property of the interactions between individuals as they pursue their own social and economic strategies" (Mithen 1991: 105) and thus as a method of *information storage and retrieval* which would help hunter-gatherers to take *decisions* that would help "increase their *chances* of *survival* and *reproduction"* (Mithen 1991: 105). Thus, patterns in faunal assemblages have been related to patterns in art representations: the risk and uncertainty generated by changing ecological conditions that affected species availability would have been partially coped with via the information gathered through their visual depiction. This would also account for the discrepancies between archaeofaunal and artistic taxa representations insofar as the latter included informative cues for two different strategies – mass-hunting and stalking of individual animals – which would leave different quantitative traces in the archaeofaunal assemblages (Mithen 1991: 105).

Within this framework, the *diachronic frequency distributions* of *decorated pottery* from early Neolithic Central Europe have been quantitatively analyzed in order to find out whether their *variations* responded to a "*neutral model*," in which variation is regarded as the result of *random drift* of stylistic traits, or to a "*selection model*," in which variation is regarded as the result of *biased selection* of functional traits (Shennan and Wilkinson 2001). The authors conclude that the case-study data coincide with the model involving selection, that is, bias in favor of novelty toward the recent phases of the analyzed period, and stress that "this does *not mean* that there is a *radical separation* in the real world between" *style*, "in the sense of neutral variation, and *function*, in the sense of variation under selection. In the present study it is clear that *both drift and selection are operating*" (Shennan and Wilkinson 2001). Also, analysis of the *tempos* in portable art production can show the *pace* at which *variability* increases or decreases diachronically and thus unveil the *rates of change* of a decorative repertoire and their links to underlying social, technical, and/or economic factors (Fiore 2011).

Another approach based on ecological-evolutionary ideas is the *ethological* conception of art, which focuses on the *behavioral* aspects of making art, or "*artifying*," and their adaptive underpinnings: for example, their capacity as *pleasure sources* and their occurrence under

crucial life concerns are seen as reasons for the reproductive success of this behavior within the human species and of the human species along its evolution history (Dissanayake 2008).

Some of these concepts have been criticized for their naturalization of human actions, which entails a passive conception of people as entities behaving only according to biological conditions. However, people not only create cultural variability but also have a certain influence in the selection conditions of such variability: this conception allows for researching human agency underneath art production, continuity and change, at long-time scales characteristic of the evolutionary framework.

Key Issues/Current Debates

Several debates are currently developing within the archaeology of art arena, of which three are outlined here. One regards the reasons *why* such production occurred, which have mostly been related to human *cognitive capabilities* (including rational, perceptual, emotional, manual-skill, mnemonic, and neurological factors) and to the *potential symbolic functions* of visual images and their *adaptive and social implications* (Davis 1986; Chase and Dibble 1987; Davidson and Noble 1989; Mithen 1996; Conkey et al. 1997; Bednarik 2003; Hogdson 2006). Another revolves around whether art has been created exclusively by *Homo sapiens sapiens* (Mellars 2005) or whether it has also been created by *Homo sapiens neanderthalensis* (D'Errico et al. 1998), the latter possibility being slowly strengthened by early finds not attributable to the former species.

Finally, due to their strong aesthetic appeal and social implications, art materials often tend to be considered as valuable *cultural heritage* by *researchers, local communities*, and the *general public* (Loubser 2001). This situation sometimes entails conflicts of interest but also bears the potential of enriching the conservation, uses, and knowledge of this heritage if proper and mutually respectful dialogues among all the concerned agents are developed.

International Perspectives and Future Directions

The current theoretical panorama in the archaeology of art is quite heterogeneous, given that several of the above-mentioned frameworks are currently being used by researchers. It is clear that some of these frameworks have similar ontological and epistemological roots, making them complementary, while others are incompatible due to the fact that their perspectives contradict each other in the way they define and conceive art and/or in the way they have devised its analysis and interpretation. Moreover, different perspectives do sometimes approach the same topic from different points of view – for example, information transmission through art has been tackled from processual, post-processual, social, semiotic, and evolutionary-ecological approaches – and these approaches to such topic may or may not be complementary according to the ontological and epistemological similarities or differences discussed above. A combination of different frameworks can often be viable and relevant where they are not mutually contradictory in their core concepts and methods. Through this critical panorama, the reader can follow those approaches of his/her interest and explore, pursue, and link their paths in order to shed new light on ancient art.

Archaeology of Childhood

Jane Eva Baxter
DePaul University, Chicago, IL, USA

Introduction

Archaeologists always have been aware of the presence of children in past societies, particularly through their skeletal remains in mortuary populations. Traditional archaeological interpretations, however, have overlooked children's contributions to the archaeological record and as members of past societies. The archaeology of childhood is an area of inquiry that has grown significantly over the past 25 years to redress the absence of children in archaeological interpretation. This area of scholarship encompasses the study of childhood as a culturally defined stage of the human life cycle and research on children as cultural actors.

Definition

Viewed cross-culturally, childhood is a period in the human life cycle defined differently in each culture. Sources show that individuals embodying that category of personhood, children, make significant contributions to their families, communities, and societies in social, economic, and symbolic capacities. The archaeology of childhood embraces these views of children and childhood and works to develop method and theory that enables an understanding of children in their own right and also to investigate how the study of children can provide unique perspectives on life in the past more generally.

Key Issues/Current Debates/Future Directions/Examples

The archaeology of childhood has a singular history in terms of timing, but in reality many different areas of archaeology have developed a sensibility toward the study of children through unique disciplinary trajectories (Lillehammer 2015). In anthropological archaeology, studies of childhood emerged as an extension of feminist critiques in the 1980s and 1990s that exposed the neglect of women in archaeological analyses. Interpretations of the past that excluded women were considered inaccurate and incomplete, and the same argument was later made for children (Baxter 2008). Classical archaeology's interest in children and childhood developed from that discipline's enduring interest in Greco-Roman families, family structures, and family life (Bradley 2013). The remarkable fluorescence of work on the bioarchaeology of childhood builds on the long-standing inclusion of immature or "subadult" human skeletal remains in mortuary analyses and addresses intersections of social identity and meaning with biological development (Lewis 2007). Research on children and childhood in historical archaeology has been integrated into broader research topics including education, households, and parenting, as well as site-specific studies at orphanages, schools, brothels, and socializing institutions, but a reliance on readily identified child-specific material culture in the documentary record has limited many such studies (Wilkie 2000). Integrating children into archaeological interpretations has required two main developments; the first applies to the value of childhood as a subject of study and the second to the visibility of children in the archaeological record.

First, archaeologists have had to question their own assumptions about the nature of childhood and the physical, social, and cognitive capacities of children (Sofaer Derevenski 2000). Limitations on archaeological thinking about children and childhood stem from individual experiences of childhood and the dominant cultures around child-rearing experienced by archaeologists themselves. Many contemporary constructions of childhood emphasize the preparatory nature of childhood, particularly on how play and formal and informal education are not about constructing experiences during childhood as much as socializing and instructing children for their futures as adults (Baxter 2016). This type of thinking traditionally has led to the assumption that adults were important social actors in the past, while children were relatively insignificant and not worthy of archaeological study (Sofaer Derevenski 2000; Baxter 2008). The archaeology of childhood questions this fundamental assumption.

One of the ways archaeologists have challenged this assumption is by turning to the ethnographic and historical records to find cross-cultural examples of childhood that illuminate the diversity of childhood experiences and the possible roles and opportunities for children in the past. These sources have revealed significant variability in how cultures define childhood and stages of childhood, as well as the important and unique contributions children make to the economic, ritual, and social lives of their communities (Kamp 2002). Ethnoarchaeological work focused on children has further demonstrated their contributions to the economic activities and social lives of communities. Bird and Bliege Bird (2000) studied the foraging behavior of children and adults among the Meriam of the Eastern Torres Straits. They found that children used their small body size and particular agility to access different types of prey in coastal gathering events than adults who foraged in open spaces and deeper waters. The shell middens that were the archaeological signatures of these foraging events included distinct patterns of adult and child foraging, both in terms of prey choice and processing strategies. This work illustrated the impact children's behaviors can have on a group's overall economic strategy and also on the archaeological record. Ethnoarchaeological work on children's play in Northern Ghana demonstrated that children used material culture and space in unique and innovative ways that were often at odds with adult expectations and strictures (Casey and Burruss 2010). Children in this study created play spaces and accumulated found objects for imaginary game play focused on food preparation that reflected an awareness of and willingness to challenge the social structures present in their culture as a whole. Play in this context was not only preparatory, but also innovative and agentive, as well as archaeologically visible through the creation of distinct spaces devoted to play.

Second, archaeologists have expanded theoretical and methodological approaches to identify the presence of children in the archaeological record. Many of the earliest attempts to locate children in the archaeological record focused on miniature objects assumed to be toys or playthings, and archaeologists still tend to equate the, visibility of children archaeologically with the presence of artifacts identified as toys. This view has been critiqued as oversimplifying children's engagement with the material record, artificially separating objects into separate spheres of adult/child, and transplanting contemporary ideas of children's activities into the past (Crawford 2009; Baxter 2016; Wilkie 2000). While toys and play are still considered important aspects of children's lives, more recent approaches combine ethnographic and historical evidence for the types of roles and behaviors that might have been available to or expected of children in a particular culture and research on the cognitive, behavioral, and psychological development of children more generally.

For example, many studies have focused on children as learners, apprentices, and innovators in craft production and have found evidence for novice craft production in ceramic and lithic manufacturing assemblages (Crown 2010; Finlay 2015). One aspect of this type of study emphasizes how novice crafters engage in the process of manufacturing and working with materials. Differences in raw material use, precision and dexterity in manipulating materials, and

consistency in process and output are roughly identifiable by age and can be used archaeologically to distinguish between those learning to make handcrafted items and those who are expert crafters. These studies also present ideas about how children can participate in crafting communities when not directly working in their apprenticeship. Helping to gather raw materials, cleaning workspaces, and spending play and leisure time among crafters are all ways children are recorded ethnographically and historically as being a part of crafting communities and offer ways to integrate children into interpretations of work and workspaces encountered in the archaeological record.

Interpreting archaeological sites without relying specifically on toys and playthings to identify children has involved relational approaches that explore how landscape and architecture offer affordances and barriers to children's engagement in social spaces. At the Mayan site of Chunchucmil, Hutson (2006) used relational approaches to the landscape to illustrate the places where children likely would have spent time in work and play. Baxter (2010) looked at the placement of nineteenth-century graffiti in large tableaus of such art created by emancipated Afro-Bahamians at former plantation sites. By measuring the height of the images from the ground surface, she was able to determine that much of the art was either created by children or deliberately placed low to the ground to facilitate their engagement with the images. Dozier's (2016) study of a cache of odd objects in a pit at the margins of a farm site in Shabonna Grove, Illinois, suggested that the assemblage was the result of children deliberately selecting interesting objects for play in remote areas away from adult activities. All of these studies are examples of how archaeologists are moving beyond toys to identify children in the archaeological record, thus expanding the possibilities of interpreting their contributions to life in the past.

A final type of research has focused on understanding childhood as a category of identity and stage in the human life cycle. This type of work asks questions about how different cultural groups defined the category of child, its potential subcategories (e.g., infant, toddler, teen, etc.), and its intersections with other categories of identity such as class or gender. For example, archaeologists working in areas with well-preserved artistic traditions such as Ancient Egypt, the Greco-Roman World, and pre-Columbian Mesoamerica have studied iconographic and artistic images of young people to identity different life stages of children and the objects and activities associated with each (e.g., Beaumont 2012). While artistic renderings of people and activities often speak to cultural ideals rather than lived realities, they also create relationships between objects, spaces, and people that can be investigated through the archaeological record.

Bioarchaeological studies are another area of scholarship that has been particularly fruitful in defining categories of childhood, particularly through problematizing the relationship between biological maturation as seen in skeletal remains and socially defined age as reflected in mortuary treatment (Halcrow and Tayles 2008; Lewis 2007). A recent example of such work is Lewis's (2016) study that begins with the question, "What was it like to be a teenager in medieval England?" This study problematized the category of teenager/adolescent and explored what skeletal evidence can tell us about the health, working life, and social circumstances of young male and female adolescents before and after the Black Death of AD 1348–1349. The literature is filled with many such rich examples of how analyzing skeletal remains, burial treatments, burial placement, grave goods, and commemorative markers can be used to evaluate age-based categories of identity and the human lives being lived across the spectrum of age (e.g., Thompson et al. 2014).

A

The Archaeology of Forced Migration

Sarah Mallet
School of Archaeology and Pitt Rivers Museum, University of Oxford, Oxford, UK

Definition

In early September 2015, a photo went viral. It showed a little boy in a red t-shirt, lying face down on a Mediterranean beach. He was later identified as Aylan Kurdi, a 3-year-old Syrian boy of Kurdish origin. In June 2019, another photo went viral. It showed an adult man and a child in red trousers, lying face down in the Rio Grande. They were later identified as Óscar Alberto Martínez Ramírez and his 2-year-old daughter, Valeria. Between the death of Aylan Kurdi and those of Óscar Alberto and Valeria Martínez Ramírez, it is estimated that 17,992 people lost their lives attempting to cross a border somewhere in the world (Missing Migrants Project 2019). (It is however important to note that the number of deaths has likely been underestimated (IOM press release).) In 2014, the UNHCR reported that the number of displaced people was the highest it had been since the Second World War, and everything indicates that the number keeps

growing with 70.8 million reported displaced people in June 2019 (UNCHR 2015, 2019).

The "right to seek and to enjoy in other countries asylum from persecution" is enshrined in the 1948 United Nation Universal Declaration of Human Rights (UDHR 1948), which recently celebrated its 70th birthday which much pump. Yet, the political response to the mass displacement of people around the world has always been fraught with attempts to evade the obligation to offer asylum (Mayblin 2017). This hostile attitude to refugees is particularly visible in – but not limited to – the Global North and has had a distinct material impact on the world. The erection of walls, fences, and checkpoints on the world's visible and invisible borders, the proliferation of refugee camps, and the complex transnational flow of materials between refugees, humanitarian and/or state actors, border guards, and "vigilantes" are all events shaping our landscapes and our response to it.

Like the study of traditional heritage, the materiality of forced displacement is a window into the temporal and spatial processes at play. Investigating forced migration through the practices and methods of archaeology differs to other methodological approaches by allowing a focus on the "physical manifestation of politics" (Herz 2013, 12). Herz (2013, 12) points out that the principal ways of investigating refugee camps are "as spaces of humanitarianism or a state of exception," but his focus is on "understanding the camp as they are used by the population" by simply asking the question: "How do people live in camps?" Similarly, archaeology asks how people lived in any given space and time, and extending the focus beyond the camp, archaeology can be an important tool to investigate the "physical manifestation of [the] politics" of forced migration.

I suggest that an archaeological approach focuses on (1) a global *longue durée* examination of how past contexts still resonate today; (2) the material entanglements between people, landscape, and objects in the context of forced displacement; (3) the unique ability of archaeology to engage an audience and "illuminate" the reality of forced migration (Gokee and De León 2014, 135). By creating an archaeological record and an archive of these materials, we can bring the experience of border crossing and displacement into our collective human heritage and ultimately can shift the perception of displaced people "as producers of valued materiality, worthy of attention, collection, and study" (Hamilakis 2016).

A note on terminology is necessary here. In recent years, the distinction between "refugees" and "migrants" has dominated political debates (Edwards 2015). The argument is as follows: refugees, fleeing war and persecution, are entitled to asylum and state protection, as outlined in the 1951 United Nations Refugee Convention; while migrants are "merely" seeking to better their economic prospects (Edwards 2015). The distinction between "refugees" and "migrants" is often an attempt at defending xenophobia and anti-immigrant sentiment: the refugee is deserving of help, the migrant is not (Edwards 2015; Hamilakis 2016). The issue of how to call people forced out of their countries has long been problematic: in 1943, Hannah Arendt opened her "We Refugees" essay with "In the first place, we don't like to be called 'refugees.' We ourselves call each other 'newcomers' or 'immigrants.'" (Arendt 1943). The term "refugee" has also been criticized for its passiveness: it implies that people *were forced* from their home and that they had no agency in their decision to leave (Greussing and Boomgaarden 2017; Brettell 2000). The term "migrant" suggests a more active decision process, albeit one that borders on criminality (Hamilakis 2016). However, taking into account that so-called economic migrants often want to escape low-level warfare, extreme poverty, political instability, unrest or dictatorship that curtail life options, and climate catastrophe, it is debatable whether the distinction between "refugee" and "migrant" is relevant, or even appropriate. However, the distinction should nonetheless not be erased: it remains significant in the Global North and shapes the political, cultural, and social discourse around forced migrations (Ong 2003). Maybe a case could be made to call them "expatriated" or "expats" in the manner in which wealthier (and often whiter) migrants from the Global North are referred to.

Here, I will use both "refugee" for people whose refugee status has been legally recognized and "migrant" for people whose status is unsettled. I will also use "forced migrant" and "displaced population" while recognizing that the terms are problematic as they suggest a lack of agency in the decision to leave one's homeland.

Background

The notion of "refugee" is fairly recent, with an oft-cited argument that French Huguenots escaping religious persecution may have been the first modern refugees (Hintermaier 2000). Refugees became ubiquitous in the twentieth century, leading George Steiner to talk of an "Age of Refugee" (Said 2013), and it looks like it will continue into the twenty-first century, as the number of displaced people keep growing (UNCHR 2019). While it is interesting to understand the history of the figure of the refugee, it is beyond the remits of this entry, and what is of interest here are the recent events leading up to the So-called 'refugee crisis' of 2015–2016.

While media interest peaked in the summer of 2015, and turned the plight of people fleeing war and persecution into a spectacle, the beginning of the so-called crisis had indeed started a year earlier when UNHCR reported 59.2 million forcibly displaced people, the highest number since the end of the Second World War in 2014 (UNHCR 2015), which is also when the *Missing Migrant* Project started recording migrant deaths. Migratory pressures were particularly visible in the Mediterranean and at borders of the Schengen Area. Elsewhere in the world, the Rohingya refugees fled Myanmar in large numbers in early 2015 and 2017, and the number of death on the US-Mexico border also increased (Sánchez Dionis and Dearden 2019, 6, 25, 28). The question of migration dominated political debates in 2015 and 2016 both in Europe and the United States, with the United Kingdom referendum to leave the European Union and with the presidential campaign of Donald Trump.

The reasons – the push and pulls – for the displacement of people are varied and complex and beyond the scope of this analysis (see, e.g., Van Hear et al. 2018). What the archaeology of forced migration focuses on instead are the material entanglements between displaced people and the world and how these entanglements echo long-term interactions between humans and their surroundings.

Key Issues

While contemporary archaeology might seem like an oxymoron, archaeological approaches have increasingly been applied to the studies of modern issues, including forced migration. Work has focused on camps (Dreyer 2001; Myers 2008; Burström 2009; Ramadan 2012, Hicks and Mallet 2019), shelters (Kiddey 2019; Fredriksen 2014); or objects (Bergqvist Rydėn 2018). The Undocumented Migrants Project (De Léon 2015), which has investigated how the landscape is used by and against those who attempt to cross it, has also been particularly influential. Here, the focus will be on four specific aspects of the materiality of forced migration: (1) landscape, (2) boundaries, (3) camps, and (4) objects. There are many more avenues for an archaeology of forced migration, but I contend that these four strands are a good starting point.

What is immediately striking when considering landscape in relation to forced migration is that the landscape plays two distinct and complementary roles: it is simultaneously used as a weapon against displaced people but can also be a space that needs to be protected from outsiders. The first aspect might be the most obvious one. Whether it is the Sonoran Desert in the Southern United States, the Sahara, the Mediterranean, or more recently the English Channel, features of the landscape have been used to deter people from reaching their destinations (De Léon 2015, 3; Hicks and Mallet 2019, 13, 30; Hamilakis 2016). Unsurprisingly, these policies have resulted in a very high mortality rate (Sánchez Dionis and Dearden 2019). While these numbers are only estimates, it is believed that 10,000

people have died in along the US-Mexico border since 1994, while 34,361 deaths have been recorded in the Mediterranean between 1993 and May 2018 (Sánchez Dionis and Dearden 2019, 6–52). There have been 78 deaths at the UK border in Calais, mostly traffic accidents, but 4 people have died in the Channel in the summer and autumn of 2019, making it a concern that the number could rise as many more people attempt to cross (Sánchez Dionis and Dearden 2019, 78; Sanderson 2019, Oberti 2019, AFP 2019). It is unknown how many people die each year in the Sahara: the only estimation is that of 1,703 deaths since 1996 but no official record is kept (Sánchez Dionis and Dearden 2019, 36). The local population of Agadez in Niger talk of the desert as an immense cemetery (Tervonen 2018).

That these obstacles to reach a destination are natural barriers have allowed the states to take a passive role in the consequences of their border policies, as "the environment obscures culpability" (McGuire 2013). This has been particularly visible in the United States, where the death of children was blamed on the dangers of the landscape, rather than on the policies that forced families across these dangerous places in the first place. Speaking of the death of Jakelin Amei Rosmery Caal Maquin, a little girl who died in US custody in late 2018, the then Secretary of the Department of Homeland Security Kirstjen Nielsen commented that "this is just a sad example of the dangers of this journey" (Varela 2018).

Archaeology has shown how natural boundaries have had a structuring role in the organization of the landscape (Bradley 2000, 150; McGuire 2013; Ten Harkel in prep). These barriers have participated in the construction of identity linked to territory, by seemingly making it *natural* that the landscape, and therefore its people, should be separated. In the words of McGuire, "borders inscribes sovereignty on the land" (McGuire 2013). Turning natural features into "killing machine[s]" (De Léon 2015, 3) is the most recent event in "the enduring record of -and testimony to- the lives and work of past generations" that is the landscape (Ingold 1993). The cognitive processes behind boundaries have developed from lines in the landscape to a concept of land-based identity, which mobilize the land to defend the identity (Løvschal 2014). While recent scholarship has also noted that natural boundaries and/or human-made borders were not only land divisions but also zones of communication and "fluid spaces of crossing" (Parker 2006; Loveluck and Tys 2006; McGuire 2013), the ability to "cross" or to "use" the sea as a "highway" is dependent on resources and maybe status, and not accessible to everyone (Ten Harkel in prep): this is still true today when crossing the English Channel, the Mediterranean, or the Rio Grande is fairly cheap and safe for one with a passport, but dangerous and deadly for one without.

The role the landscape plays in defending land-based identity is, however, not only active. It also plays a passive but no less important role. Indeed, the landscape is not solely used as a dangerous weapon: it is, at the same time, a fragile space in need of protection. This is particularly visible in Calais (France) where the site of the former "Jungle" camp, where 10,000 refugees lived between 2015 and 2016, has been reinvented as a nature reserve for migratory birds (Hagan 2019). It is not new that environmental concerns should be used to control migration and that nature is used to others and excludes certain groups (Doshi 2019; Ramutsindela 2015; Hultgren 2015, 36–52; Hagan 2019). The links between environmentalism and migration controls go back to postcolonial concerns of scarcity of resources due to overpopulation (Cagle 2019). As with most postcolonial legacies, racism is evident: the populations needing to be controlled are always perceived to be non-white (Cagle 2019). The idea that nature must be protected against outsiders has been a driving force of nature conservation. For example, the first national park in the United States was created with just this idea in mind. In his report to the President, Ferdinand Hayden, one of the main advocates for the creation of Yellowstone National Park, explicitly stated that "the vandals who are now waiting to enter into this wonderland, will in a single season despoil, beyond recovery, these remarkable

curiosities" (Chittenden 1915, 77). Today, this perception that foreigners are dangerous to the natural landscape is still very common (Cagle 2019) and sometimes used against migrants as an argument why they should not be let in. Tucker Carlson, a right-wing US media pundit, lost many advertisers after saying: "The truth is that unregulated mass immigration has badly hurt this country's natural landscape [. . .] Huge swaths of the region are covered with garbage and waste that degrade the soil and kill wildlife" (Bort 2018). Lynn Meskell writes of this tension between land conservation and local populations in Kruger Park in South Africa caused by colonial concept of natural parks (Meskell 2005).

Creating boundaries in prehistory was an attempt at mapping control of the landscape and protecting some of its parts from other groups (Løvschal 2014). These landscape divisions, much like natural barriers, invest people with a sense of identity with a place and separate groups between those who belong and want to *protect* it and those who do not belong and seek only to *destroy* it. These processes of landscape and identity creation are dynamic and constantly reinvented: one's identity can be articulated in relation to a street, a city, a region, a nation-state, a supranational territory, and even the entire planet, at any given time and/or simultaneously. I argue that the relationship between displaced and settled populations is articulated in and around notions of the landscape and the identities that flow from it and that archaeological investigations give both a diachronic and spatial perspectives of these people-landscape networks.

However, this mobilization of the landscape against displaced people does not mean they are without agency over it. In Calais, the creation of the "Jungle" camp was a reorganization of the landscape which happened with no oversight from the traditional state humanitarian actors (Alaux 2015). The makeshift camp grew into an urban space, with restaurants, bars, churches, and mosques (PEROU 2016; Agier et al. 2018). It existed on French soil, but outside of France. In a way, it even competed with French institutions: Calais locals would comment that bread and beer were cheaper in the camp due to the lack of taxes (PEROU 2016, 23). Outside the camp, new place names became an important tool to navigate this foreign place. "Car Park Belgium" was thus named after many people thought they were boarding trucks for the United Kingdom in a particular car park and found themselves in Belgium (Mann in prep). The name was intended to avoid future mistakes; "Car Park Sheitan" was a place teeming with police and dogs, the name here giving a clue to the danger of the place (Mann in prep). This ability to live and make use of the landscape was not deterred by the dismantlement of the camp in October 2016, with the establishment of a new network of places to find Wi-Fi, food distribution, or where to sleep and hide. A city park was even used as an "invisible church" for people to worship and conduct mass (Hagan 2019). All of these have created a geography unknown and hidden to most "legal" citizens, similar to what Kiddey (2017) described in her pioneering study of homelessness. State apparatuses are attempting to make this new geography invisible, but archaeology can render the invisible and the unrecorded visible. By investigating these landscapes through archaeological methods, we resist the injunction to look away and are forced to recognize the lives of the people who are constantly pushed into the margin of our societies (De León 2015, 3; Hicks and Mallet 2019, 31).

These new engagements between landscape and the "legal citizens" on the one hand and displaced populations on the other are only the most recent development of long-term interactions between humans and the world. The natural world played a part in structuring the human world, with natural features becoming markers of organization and identity, on which human-made borders have been superimposed. The physical existence of borders is the logical conclusion of a long-term cognitive process, which frames the ways in which people perceive spatial phenomena and social relations as being coherent separate material (Schaffer et al. 2010; Løvschal 2014). However, as argued by Barth, creating a boundary "lay(s) down some premises but does not determine all the social forms that will eventuate" (Barth 2012, 30). We can investigate

these premises through an archaeology of borders, which will allow us to take a longer view of frontier and boundaries and to focus on "subsistence strategies, social identity, colonialism, the growth of the nation-state and defence" (McCarthy 2008, 202; Lightfoot and Martinez 1995) and will also investigate borders as the material embodiment of nation-state and the physical separation between legal and illegal presence on any given territories (McGuire 2013).

Brown (2014, 25) argues that border walls "function theatrically," a conclusion that it is hard to disagree with considering the hysterical rhetoric of Donald Trump's promises to build a wall at the US-Mexico border during his presidential campaign (and his insistence that construction is underway despite evidence to the contrary). Less talked about than "Trump's wall" but no less significant – or less theatrical – are the dozens of current and proposed construction projects for national border barriers from the Mexico-US border to borders between Norway and Russia, India and Bangladesh, Afghanistan and Pakistan, and Turkey and Syria or the "berms" built by Morocco in the Western Sahara (Hicks and Mallet 2019, 25; Garfi 2014). This global wall-building moment is unprecedented: 30 years after the fall of the Berlin Wall, after the de-bordering of the Schengen Area but also of parts of Africa with the Economic Community of West African States, it now seems impossible to argue that the post-Cold War world is increasingly borderless. On the contrary, small pockets of border-free territories are gradually encircled with more and more barbed wire. Even Schengen is not the border-free zone than it once was, with controls reinstated [in some countries] thus limiting freedom of movement.

One of the main arguments for the rise of all these walls, put forward by Brown (2014, 24), is that this is the reaction from nation-states who are losing their sovereignty. This is particularly convincing since, while walls are the physical embodiment of nation-states, they are actually often dematerialized to "buffer zones" (Amnesty 2014), demonstrating how their purpose is not to protect the nation-states from other state actors but rather an attempt to control transnational flows that are not state-sponsored (Brown 2014, 21). It is indeed fascinating that modern borders do not necessarily map on to modern nation-states. For example, the physical border in Calais is an "an intra-European laboratory for an EU external border regime" (Hicks and Mallet 2019, 25), and in effect Europe has outsourced its border management and control to "buffer zones" such as Niger, Libya, or Turkey (Amnesty 2014). While Berlusconi was widely condemned for commenting that his 2007 deal with Libya (still under Gaddafi's regime) would mean "more oil and less migrants," most of European border deals actually follow the same model by giving money to third countries to let them handle the migratory flows (Andersson 2014, Hamilakis 2016).

However, the dematerialization of borders outside of the nation-state that they physically represent is not the only change to modern border regimes. There is an emerging tendency for borders to take on a range of different forms and even locations (Jones 2012). While this might be tempting to see this as a recent development brought on by the War on Terror launched by the United States after the attacks on the World Trade Center in September 2001, it was already changing before as noted by French philosopher Etienne Balibar who wrote "No longer simply located at the edges of territories; they are distributed all over the place, wherever the movement of information, people and things takes place, where is controlled, for example in cosmopolitan cities" (Balibar 2001 [1999], 15; Translation Hicks and Mallet). An archaeological approach focused on landscape and materiality is an attempt to map on to this new kind of borderwork, which goes beyond natural and human-made barriers but also exists in less monumental forms, such as paper. For example, the lack of specific pieces of paper has created the status of the *undocumented*, revealing of the developing importance of paperwork, a border materialized through the physicality of a different material (Hamilakis 2016).

It is argued here that the terminology used to discuss the "*undocumented*" *or* "*illegal*" *migrant* is revealing of the postcolonial legacies

of the border systems in the Global North. "Undocumented" immigrants are considered to be without documentation because postcolonial bureaucracies have often made the documentation of their country of birth worthless. It is true, however, the recent toughening of immigration politics in Europe has led some displaced people to burn all identity papers to avoid deportation back to the country they come from (Andersson 2014; Hamilakis 2016), but even in these cases, it is unlikely that we will ever see a class of truly undocumented citizens: as the steel border has been reinforced by the paperwork, paperwork has been reinforced by our own bodies, and we carry the border within us in our biometric world (Ramutsindela 2015). Fingerprinting and DNA used for testing family reunification are tools to control migratory flows that rely solely on the materiality of our bodies, when desert, steel, and papers have failed to contain displaced people "outside." This development, of course, is recent. But like the lines in the landscape of the Bronze Age, it is part of the same cognitive process of ordering the world between "us" and "them." The use of DNA in archaeology is fraught with theoretical issues, especially regarding its link to identity. This was illustrated when a paper by Feldman et al. (2019) was taken as conclusive proof by Israeli Prime Minister Netanyahu that Palestinian populations had not originated from Israel (Jaffe-Hoffman 2019). The relationship between land, identity, and bodies is a complex, ongoing process, which archaeology can contextualize and help clarify notion on population homogeneity and the origins of nation-states. The use of archaeological data in the political discourse of exclusion, racism, and xenophobia is evidence that archaeologists are needed to reframe the conversation on the relationship between the materiality of the body and identity.

Another important focus of the archaeology of forced migration is the archaeology of camps. Many studies (Dreyer 2001; Myers 2008; Burström 2009; Ramadan 2012, Hicks and Mallet 2019) have investigated how an archaeological approach can shed light on the materiality of the camp. Archaeology allows us to consider the space of the camp beyond that of a state of exception and to investigate the *longue durée* processes that have led to the creation of a camp in the first place as well as the complex spatial ties between the camp and the landscape it inhabits. An archaeology of refugee camps can start from the simple question of what survives once a camp is dismantled to the more complex ones of the social organization of a camp through its materiality: who controls resources, how are the shelters built, and how does the flow of materials between the different agents are organized. Camps are designed as temporary space, and this impermanence becomes a form of control, justifying destruction, dismantlement, and destitution, thus generating an ultra-short-term history (Hicks and Mallet 2019, 50). Archaeology allows to record and to give values to these temporary places. As Burström (2009) argues, "it brings the question of remembrance to the fore." Indeed, because camps are meant to be temporary, then they are not meant to be remembered. This is part of the process of invisibilization mentioned above – but by contextualizing them in an archaeological framework, we can inscribe them in the wider context of human heritage.

Finally, beyond the materiality of landscapes and borders and camps, it is also imperative to consider objects, who can speak of lives and event not otherwise recorded. At the UK border in France, instances of violence are regularly denounced but denied by both states (Refugee Info Bus 2018; E. Macron, *Discours à Calais* 16th January 2018), but the material evidence of this violence is overwhelming. Tear gas canisters were scattered all over the camp site and were picked by volunteers and refugees in very large numbers after the camp dismantlement. These canisters – as well as the rubber bullets also present on site – are direct evidence to the force used by the French police, as well as the tactics of using out-of-date tear gas, since the canisters range from 1993 to 2016. Much higher batch numbers in 2015 and 2016 suggest a significant increase in production at that time by the two different French manufacturers (Nobel Sport and SAE Alsetex). Further investigations are currently under way to correlate this

increase to the situation in Calais (Mallet and Fowler in prep).

But objects are at their most powerful when they act not as testimony of violence but as witness to humanity, when they are used to rehumanize refugees by giving back them their name, and their identity, even after death. One of the largest operations to identify the bodies of migrants. The Italian Prime Minister at the time decided that the bodies should be identified (Bromwich 2019). This mammoth task has been undertaken by the team of Christina Cattaneo in Milan, attempting to give back their identities to people who would otherwise be forgotten. Through their work, encounters with objects have allowed for the rehumanization of refugees, when the landscape, the borders, and political discourse only attempt to dehumanize them. I argue that the materiality of forced migration forces us to face the humanity of those we leave to die at the borders of our nation-states. When it is reported that a 14-year-old boy from Mali kept his school report sown inside his jacket, fragments of his identity – that of an excellent student, probably hoping to resume his education once he was safe in Europe – shine through and remind us that his death in the Mediterranean in April 2015 is not a statistic but a tragedy.

Conclusion and Future Work

This is only a brief overview of how archaeology practices and methodologies can further the study of forced migration. Archaeology is a powerful political tool with which to bring the stories of migrations and refugees into our lives and to further tolerance and acceptance with society. It also allows to place migrations into the *longue durée* context of human movements and reminds us that the present moment is not exceptional, but a part of a wider, global, and continuous pattern of movement. Focusing on landscape, borders, camps, and objects, we can investigate how the political discourse in the Global North has a material impact on the world. It also allows us to understand and contextualize this material impact and how it affects lives and causes death across the globe. By giving a framework into which one can examine the entanglement between people, landscapes, and materials, archaeology is particularly powerful to address the question of forced migration.

Archaeology of Kalkriese

Achim Rost[1] and Susanne Wilbers-Rost[2]
[1]Department of History, Ancient History/Archaeology, Osnabrück University, Osnabrück, Germany
[2]Department of Archaeology, Varusschlacht im Osnabrücker Land gGmbH, Museum und Park Kalkriese, Bramsche-Kalkriese, Germany

Introduction

Kalkriese is the name of a community in the northwest of Germany, circa 20 km north of Osnabrück. Today, this name also stands for an extensive battle area, dating from the time around Christ's birth. Most likely, the Varian Disaster was taking place here in 9 A.D.

Archaeologists began to focus on Kalkriese in 1987 when field surveys with metal detectors helped to discover a hoard of 170 Roman denarii and soon thereafter Roman military equipment. The latter suggested that a place of military conflict had been discovered, while the denarii pointed to 9 A.D. Thereby earlier finds of Roman coins were also validated, which had been found by local farmers working their fields as early as the seventeenth century, and held at Barenaue Castle, home to a noble family in the region. Even the historian and Nobel Prize winner, Theodor Mommsen, concluded from these coin findings that the Varian Battle occurred in this spot (Mommsen 1885).

Definition

With the systematic archaeological research that took place in Kalkriese since 1987, it was the first time that an ancient battlefield and the wider context of the conflict landscape was investigated. The site helped in the development of modern archaeological techniques and methodologies for the archaeology of battlefields. As a case study, Kalkriese is particularly suitable because the military equipment of the Roman troops found here is rich in metal and rather unique, especially the weaponry of the legionaries, which allow for identification despite fragmented record.

Historical Background

The Varian Disaster is known due to written records of ancient writers such as Tacitus (Publius Cornelius Tacitus, Annales I, 59–62 = Ab excessu divi Augusti), Cassius Dio (Lucius Cassius Dio Cocceianus, ΡΩΜΑΙΚΗ ΙΣΤΟΡΙΑ 56, 18, 1–24), Florus (Publius Annius Florus, Epitomae de Tito Livio bellorum omnium annorum DCC 2, 30, 29–39), and Velleius Paterculus (Velleius Paterculus, Historia Romana 2, 117–119). In line with Emperor Augustus' policies of expansion, Germanic territories to the right of the Rhine were

meant to be taken under Roman control, starting with the Drusus campaigns 12–9 B.C. As of 7 A.D., this was the task of P.Q. Varus, the governor of *Germania*. In 9 A.D., an army of three legions was at the order of Varus in *Germania* east of the Rhine, in a summer camp close to the river Weser, in the territory of supposedly friendly Germanic tribes. On their way back to the main Roman camps at Rhine and Lippe, the legions of Varus were fatally beaten by an alliance of Germanic tribes. The Germanic allies were under the command of Arminius, a Germanic nobleman, who had served in the auxiliary troops of the Roman army. Despite this severe defeat, attempts at military expansion in *Germania* did not cease. It was not until the military campaigns of Germanicus in the years 14–16 A.D. that Emperor Tiberius put an end to these military quests.

At the beginning of the sixteenth century, the annals of Tacitus were rediscovered at Corvey Abbey. In this work, the defeat of Varus was referred to as the Battle of the Teutoburg Forest, and Arminius was named the liberator of *Germania*. Consequently, this event has for centuries been deemed to be of national significance, and there were many attempts to establish its location.

Key Issues/Current Debates

The History of Research

Systematic metal detecting was yielding further coins and military equipment at various locations in Kalkriese and the surrounding area (Fig. 1) soon after the discovery of the initial hoard of denarii. In 1989, first excavations took place at the Oberesch site, where successful prospections had been taking place that resulted in various finds. Even the first trial sections showed that Roman artifacts were present in their original positions underneath the layers of soil that were being used agriculturally. Once the excavations were extended, another significant discovery was made alongside the military equipment that was

Archaeology of Kalkriese, Fig. 1 The area of investigation at Kalkriese and the topography; No. 1–5: indigenous settlements around the time of Christ's birth. (Copyright: Klaus Fehrs (Museum und Park Kalkriese), Achim Rost, Susanne Wilbers-Rost)

found, a rampart. Due to the dispersal of the artifacts, this was soon interpreted as an ambush by the Germanic tribes. The coins and military equipment that were found were deemed to be remains of military conflict between Romans and Germanic tribes in the Augustan period. It was supposed that these finds were relics of the Varian Disaster, especially since more and more sites with Roman finds were localized in the vicinity, indicating an extended battle area.

Traces of military conflict were found in an area of circa 30 km^2 on terrain that bridges low mountain ranges and the plains of northern Germany. The area in question is characterized by a natural strait between the Great Bog (Großes Moor) in the north and the Kalkriese Hill (Kalkrieser Berg; up to 160 m above sea level in height), a foothill of the Wiehen Mountains (Wiehengebirge), in the south. Between these terrains that are not easily passable, there is a topographic depression of 1.5 km in breadth. It was highly wet in large parts, which suggests that a passage about 2000 years ago was merely possible at the lowest part of the mountain's slope, and on a sand ridge at the southern edge of the bog. At the most narrow point of the natural strait and at the lowest part of the mountain slope (circa 60 m above sea level), the Oberesch site can be located as the main site for the archaeological finds pertaining to the vast battleground.

Excavations at the Oberesch Site

Features

At the Oberesch site, a field of circa 400 × 100 m across, the features that are directly related to military conflict in the area of Kalkriese were located: the rampart and several pits with skeletal remains of humans and animals (Fig. 2; Wilbers-Rost et al. 2007; Rost and Wilbers-Rost 2012).

The Rampart The rampart presents as a zigzagging structure of circa 400 m in length from east to west, between two creeks. It is no longer visible above ground level due to layers of soil, the so-called Plaggenesch. The practice of

Archaeology of Kalkriese, Fig. 2 Kalkriese-Oberesch: Sections (No. 1–47), rampart, pits with bones (Grube = pit No. 1–8) and Roman finds. (Copyright: Klaus Fehrs (Museum und Park Kalkriese), Achim Rost, Susanne Wilbers-Rost)

Plaggenesch was common in northwest Germany since medieval times and ongoing until the twentieth century. Sod (called Plaggen in German) were used as a bedding in stables and blended with the excrements of farm animals. Then they were utilized to ameliorate areas of agricultural soil that had lacked nutrients. Layers of soil with a thickness beyond 1 m were therefore created and often prevented archaeological finds from being discovered.

Excavation work showed that the wall was erected using sod, sand, and in parts limestone. Initially, the wall measured circa 3 m in width and almost 2 m in height. Today, the remaining structure is 0.3 m in height due to the levelling of the rampart and erosion, and a slight 15 m wide rising can be detected. At least parts of the wall were bolstered by a wooden parapet. On the southside of the rampart, there were in some sections a row of short ditches and pits of various depths but not a continuous trench. Since the wall was partly erected above consolidated rock covered with water resistant silt, the pits and ditches were meant to facilitate drainage of rainwater from above that could have otherwise flooded the structure. In places where the ground is sandy, there was no such drain. The structure of the rampart also displays discontinuations in the form of several passages, one of which is constructed as a gate. The ends of the wall which are pointing northeast resp. northwest towards the aforementioned creeks had trenches at their northsides. There is a zone without any Roman finds below the wall material, which is interpreted as the original base of the rampart; this indicates that the wall was erected before the arrival of the Roman troops and the beginning of combats. Its relatively instable construction suggests that it was built only for temporary rather than long term use.

The unusual construction on the Oberesch site does not display the characteristics of Roman military camps and is therefore being interpreted as an entrenchment of Germanic origin. It served as a means of strengthening the preexisting environmental and topographical conditions of the bottleneck between hill and bog that facilitated a military ambush. Its function was offensive rather than defensive as it allowed attacks on Roman troops that were passing by. The passages in the rampart's structure allowed northward sorties, and quick retreats into the safety of the entrenchment, if Romans attacked. The zigzagging line of the wall also allowed to encircle the Romans from the rampart when the enemies organized counterattacks.

Since there have been questions concerning the interpretation of the rampart as being a Germanic construction, there have been trial sections at the Oberesch site since 2016 to investigate, if there are further wall-like structures that may point to a Roman construction. However, this theory could not be substantiated by evidence.

Pits with Bones Alongside several bones in the former occupation layer, including skeletal remains of mules and horses, eight pits containing human and animal bones were discovered at the Oberesch site. In those pits, there were no full skeletons but single bones and skeletal fragments (Fig. 3).

Osteological investigations concluded that the human bones in question, with the exception of a female pelvic fragment, belong to males age circa 20–40. The animal bones belonged to horses and mules. The bones had lain on the surface for 2–10 years before they ended up in the pits. The bad condition of the bones does not allow for DNA-analysis, where the human bones are concerned, which prevents conclusions about the origin of the deceased. Specific injuries, however, caused by traumatic blows point to soldiers fallen in battle. The mule bones can be ascribed to mules belonging to a Roman baggage train. Isotopic

Archaeology of Kalkriese, Fig. 3 Kalkriese-Oberesch: Bone-pit No. 5; in the center, there is a human skull. (Photo: Museum und Park Kalkriese, Dept. of Archaeology)

analyses suggest that some of the animals had been living in Mediterranean areas only few months prior to their death.

The bone pits can be associated with Tacitus' account (Annales 1, 62) of a burial ceremony in the year 15 A.D. according to which Germanicus visited the battle site with his troops to bury the fallen soldiers of the Varian Disaster. Tacitus refers to a burial mound that has not yet been discovered. Specifically placed burial or sacrificial objects have not been observed in the pits. However, by depositing the skeletal remains in the pits and covering them with earth 6 years after the battle, due diligence was done towards the deceased (Rost and Wilbers-Rost 2017a, b, 2018).

Finds

At the Oberesch site, more than 5000 Roman objects were discovered (compare Fig. 2), which is the biggest volume of all Roman finds of the Kalkriese area. Not only was there military equipment and weaponry of an army ready for battle among these finds but also evidence of a baggage train with wagons and their contents as well as draught and pack animals (Harnecker 2008, 2011). What is obvious is that mostly smaller fragments were found, whereas larger objects such as pioneer axes, remnants of a chest or the harness of a mule are exceptions. Fragments of helmets (Fig. 4), body armor such as chain mail and *lorica segmentata* (Fig. 5), belts, sandals, swords, daggers, spears (*pila*), and shields can be attributed to the weaponry of Roman legionaries.

Auxiliary units have been evidenced by iron arrowheads, the cavalry by spurs, horse harnesses, and most likely some lances. Medical equipment suggests the presence of medical personnel, numerous plummets the presence of teams of surveyors, and seal-boxes and styli the possibility of scriptoria. Fragments of balances and balancing weights also point to the logistics of this Roman military campaign. Entrenching tools such as pioneer axes, tools for the purpose of wood work and leather work such as chisels and scissors, in addition to tent stakes, milling stones, and personal items such as finger rings, coins, gaming pieces, brooches, knives, and spoons complete this image of a multifaceted Roman army on the move. Small

Archaeology of Kalkriese, Fig. 4 Face mask of a Roman helmet (iron with copper and silver remnants; height 17.1 cm); it was initially covered with silver foil. (Photo: Christian Grovermann for Museum und Park Kalkriese)

Archaeology of Kalkriese, Fig. 5 Hooks of chain mail (bronze), belt buckle (bronze), plate of body armor *lorica segmentata* with buckle and hinge (iron and bronze; height 18.7 cm). (Photo: Hermann Pentermann for Museum und Park Kalkriese)

fragments of transport chests, little chests, silverware and bronze vessels as well as of furniture, and ritual objects (*litui*) demonstrate that the Kalkriese finds, despite their fragmented nature, portray the diversity of the Roman troops' equipment that was in use at the time. A few brooches and a hairpin suggest the presence of women in

this military context. Two extraordinary features with skeletal remains of mules and fragments of their harnesses visualize the pack and draught animals of the baggage train. However, it needs to be stated that the largest majority of finds at the Oberesch site are small fragments of silver and bronze sheets some of which were gold-plated or displaying ornamental designs, and hundreds of iron nails whose purpose has not yet been established.

In comparison to the large number of fragments that were identified as Roman, there is only a limited number of Germanic finds, such as a bridle, a spur, and perhaps some spearheads and metal fragments of a shield. This contrast must be due to the fact that Arminius' soldiers were originally part of the Roman auxiliary troops and equipped just like Roman troops in the Varian Battle. It can thus not be determined who fought with this Roman equipment. Moreover, one should note that Germanic warriors usually possessed military equipment that was less likely to contain metal and is therefore harder to trace archaeologically. Another factor that has an essential impact on the archaeological record on a battleground is the treatment of the deceased. The Germanic troops were victorious in their own territory and hence able to recover their wounded and deceased including their equipment and bury the dead according to the rules. Such a practice reduces the corpus of finds on the very battlefield. The fallen Roman soldiers, however, were left to the arbitrariness of the enemy which also meant body-stripping. Such a brutal looting process was more likely to produce small fragments of military equipment and personal items to be lost and left on the battlefield than the acts of combat. Thus, the number of archaeological fragments that can be found is considerably high.

Dating

The Roman militaria found at Kalkriese match the corpus of finds of other Roman places from late-Augustan times. Nearly 2000 Roman coins were found in the area and allowed for a more precise dating (Berger 1996, 2009). With the exception of a few coins from the late first to the fourth centuries, which originate in the later phases of Germanic settlement, *denarii* and *aurei* of the Gaius/Lucius type (produced ca. 2 B.C.–4 A.D.) are the latest ones. Where copper coins are concerned, the asses of the first altar series from Lugdunum (7–3 B.C.) are the youngest ones to be found. Several copper coins display countermarks, many with the VAR countermark, which points to Varus (Fig. 6).

These countermarks were most likely produced when Varus had become governor, and they define a dating of the Kalkriese finds as of 7 A.D. Younger coins like the 9/10–14 A.D. asses of the second altar series from Lugdunum were not found at Kalkriese. The coins found are therefore likely to originate in total from 7–9 A.D. which makes it highly probable that Kalkriese was the site of the Varian Battle. At present, there is discussion pertaining to the question of whether a direct connection with the military campaigns of Germanicus (14–16 A.D.) can be ruled out. In line with this, the datings of the coins are being questioned. It is being argued in this instance, that coins produced in 9/10 A.D. had simply not made it to the Rhine region, which means that there is no way of distinguishing the coins of the armies of Germanicus from those of Varus' troops. Extensive analyses of the countermarks are ongoing and may eventually bring the desired clarity in this matter

Archaeology of Kalkriese, Fig. 6 Roman copper coin (As) of Augustus, produced 7–3 B.C., with countermark VAR. (Photo: Christian Grovermann for Museum und Park Kalkriese)

(Werz 2018; Wigg-Wolf 2018; Wolters 2018). Additionally, investigations relating to the metal objects found at Kalkriese and other Roman military sites of that time hope to establish the origin of the troops that perished at Kalkriese.

What is special about the finds at Kalkriese is that they relate to a particular event. In contrast to finds from military camps that were used in the long term the artifacts at the battlefield in Kalkriese show rather comprehensively which equipment the Roman army utilized at the beginning of the first century A.D. The location of the battle area, far from Roman settlements and military camps, ensures the character of the assemblage of Roman artifacts at Kalkriese as a "closed find." This makes for chronological relevance where the dating of Roman militaria is concerned.

The Spatial Distribution of Finds at the Oberesch Site

The extensive number and versatile nature of Roman finds at the Oberesch site serve as a foundation for a detailed analysis of the finds' distribution. This resulted in insights pertaining to the events at the battleground which had led to the dispersal of the finds (Rost and Wilbers-Rost 2012, 2015).

The various kinds of military equipment are dispersed in different ways, and the likelihood of encountering a particular artifact does not correlate with the frequency of its appearance in the equipment of the Roman soldiers. For example, there is only one fragment of a sword blade, although, these weapons were an integral part of the military equipment of each Roman legionary. In contrast, fragments of scabbards, shields, and *pila* (spears) were far more commonly found. It is important to bear in mind, however, that today's dispersal of finds was a result not only of the acts of combat during the battle but also of post-battle processes such as looting. Therefore, as far as the analysis of the finds' distribution is concerned, it is not merely the original purpose of a Roman military artifact in the army or during the fighting that is significant but rather the manner in which it had been transported and how it presented itself to the looters after the battle.

Dispersed relatively equally across the investigated area were nails of the legionaries' sandals, coins, and brooches, which point to the movement of the Roman soldiers in combat. Equally widely dispersed are fragments of equipment fixed to the body such as chain mail, *lorica segmentata*, belts (Fig. 7), and scabbards. These could be discovered close to the rampart and across the whole field as well. They indicate spots where wounded soldiers were looted and dead bodies were stripped after the battle. However, the remarkable concentration of shield fragments, especially metal edgings, near the rampart (Fig. 8) cannot be related back to the events and losses of the very fighting and body-stripping.

It is likely that processes following the combat had an impact on this distribution pattern. Since the large shields of the Roman legionaries did not suit the Germanic soldiers' weaponry, they were not reusable for the victors and hence taken apart. The looters would leave the wooden parts and take the metal pieces to transport the scrap metal more easily and recycle it. The rampart as a central place at the battlefield was suitable to serve as a workspace for taking metal fittings apart. Concentrations of small fragments of silver and bronze sheets as well as nails suggest that various types of objects were scrapped there, too.

Likewise fragments of helmets were most often discovered in close proximity to the rampart. Helmets, however, consisted mainly of metal and it would not have been necessary to take them apart for easier transport. This suggests another move by the Germanic victors, namely a display of enemy weapons close to the rampart. Similar to a Roman victory monument (*tropaeum*), the Germanic victors may have collected and displayed enemy weapons to mark their victory. Depictions on the Trajan's Column suggest that shields and helmets would have played an important role in the concept of such a *tropaeum*. Arminius and his auxiliary troops might have been familiar with Roman victory rites, and may have adapted them for their own purpose, before the booty was dispersed amongst the winners. Tacitus reports on Arminius' speech following his victory and the mockery of the Roman standards by his Germanic followers. This

Archaeology of Kalkriese, Fig. 8 Kalkriese-Oberesch: Distribution of fragments of Roman shields and helmets. (Copyright: Klaus Fehrs (Museum und Park Kalkriese), Achim Rost, Susanne Wilbers-Rost)

may be interpreted as a part of the aforementioned victory celebration.

Although the indicators suggesting the presence of a Roman baggage train at the Oberesch site are diverse, there are very few remains of wagons and their load. This is likely the case because wagons and pack animals could be confiscated with their load by the victorious party and transported from the battleground. Small parts of harnesses, which were discovered at the Oberesch site, were most likely to be lost, when dead or wounded mules had to be exchanged.

A Conflict Landscape

The centrally located Oberesch with its unique features and finds can be deemed the main site in the battle area of Kalkriese, but should not be viewed in isolation, since military conflict was not solely taking place in this particular spot. Roman coins and military equipment were detected in an area of about 10 km from east to west in the narrow passage between hill and bog. However, nowhere else has a rampart such as the one at the Oberesch site yet been found. Nevertheless, excavations revealed remnants of Germanic settlements from the time around Christ's birth underneath layers of sod (Harnecker and Tolksdorf-Lienemann 2004). Since there were Roman finds unearthed on Germanic settlement sites, the question arose whether these can be deemed booty that had been transported from the battleground to indigenous settlements or whether military conflict took place at these sites. In order to evaluate the relationship between the Roman artifacts and the Germanic settlements, as well as the structure of the indigenous settlement at the time of the battle, further investigations began in 2011 (compare Fig. 1, especially No. 1 & 2). They were also intended to establish how the cultural landscape and the local infrastructure affected the course of the battle in question (Rost and Wilbers-Rost 2017b, 2019. A detailed publication is in progress).

In the area of investigation, five settlements have already been discovered, which existed around the time when the battle took place. A relatively concise dating can be made thanks to pottery with striking, thickened and facetted rims which were in use during the transition period between the Pre-Roman Iron Age and the Roman Iron Age, ca. 40 B.C.–20 A.D. The settlement sites were discovered on the lowest slopes of the Kalkriese Hill where sandy ground lent itself to agricultural use (compare Fig. 1). The slope facilitated the drainage of surface water, creeks and wells secured the fresh water supply, and the wet depression in the north, just like the Kalkriese Hill, served as a place for cattle herding and a source for timber. As was common in the northwest of Germany at this time, the settlements were single farms or small groups of farms rather than villages. On the sand ridge at the edge of the Great Bog and on top of the Kalkriese Hill, there were no indicators of settlements from around the time of Christ's birth. The settlements found in the eastern zone of the research area show a distance of circa 1.5 km to one another. Thus, the settlement clusters, that means the settlements and their agriculturally utilized areas, were closely interconnected. At all settlements in question, not only ceramics from the transition period but also from the later first century were found, which makes it likely that they were not vacated as a result of military conflict.

The events surrounding the Varian Disaster were unlikely to have been highly consequential for the civilians of the Germanic settlements. Since the attacks had been strategically planned by the Germanic military leadership, the civilians would have had the time to wait out the conflict at a spot, such as the Kalkriese Hill, that was further away from the battleground. They would have been able to take movable belongings such as personal items, stocks, cattle, and seeds.

Paths and roads can be presumed as connections between the indigenous settlements, but they cannot be detected archaeologically. Hence, the Roman army for their move westwards through the bottleneck between hill and bog would take a route along the sandy zone at the lower slope of the Kalkriese Hill. There, settlements and areas under cultivation had created forestless terrain. In times of peace and accompanied by indigenous allies, it would have been possible for the Roman troops to pass this terrain. But in the case of enemy attacks, this situation was very inconvenient for marching units since there was no alternative

route through the narrow terrain. The Germanic attackers, however, benefitted from this terrain. The edges of the forest, which surrounded the settlement clusters, provided cover in the case of partisan attacks on the Roman troops even without further entrenchments. The population density was, however, unlikely to have sufficed to withstand a Roman army, which is why the alliance between the Germanic tribes was essential to their military success.

The Course of the Battle

Unlike a siege, a pitched battle will not reveal many features, and the reconstruction of the events mainly depends on the archaeological artifacts. When paired with evidence about the settlement structures, the spatial distribution of Roman finds unearthed between Kalkriese Hill and the Great Bog allow for conclusions on the course of the battle. At Kalkriese, there is evidence of repeated attacks on marching Roman troops. To reconstruct the development of a military crisis is easier in such a battle in a defile rather than in a case of static warfare.

East of the Oberesch site various sites with Roman artifacts were discovered. The site that is furthest in the eastern direction is located about 6 km from Oberesch. However, in principle, the number of Roman artifacts found in the eastern zone of the battle area is low. This might not necessarily point to subordinate military combat. As long as the Roman units could care for the wounded and dead soldiers and could take them along in the baggage train with their equipment, there might have simply been hardly anything left on the battleground. In the east, the zone of the Romans' approach, there were few finds, mostly coins and brooches. Those were presumably part of the legionaries' field packs, which were sometimes left behind when units had to prepare for fighting and to counter sudden Germanic attacks. When the Germanic warriors looted the field packs of their Roman enemies, then small objects such as brooches and coins were more likely to fall out of the leather bags. The spatial distribution of finds at the lower slope of the Kalkriese Hill suggests that the Roman troops kept mainly to the route along the Germanic settlement area.

At the Oberesch site, the situation presents completely different from that in the east. The large number of Roman finds at this site, which is partly due to body-stripping, and the bone pits indicate that this was the section of the battle area where considerable parts of the Roman army were totally defeated. Roman soldiers who had been wounded in battle and transported with the baggage train would finally be killed here and their bodies would also be stripped by the enemy. This, too, may have enlarged the amount of archaeological finds at this site.

Most of the Roman finds west and northwest of the Oberesch site can be interpreted as the result of escape, subsequent skirmishes, and capture. The distribution of the remains stretches to the northwest about 3 km across the wet depression to the sandy ridge at the southern edge of the bog and westwards along the sandy slope of the hill as well. But in these areas, the finds are less numerous than at the Oberesch site. In the northwest, especially in the wet area, some striking valuable finds have been discovered, such as hoards of silver coins and silver fittings of a sword scabbard. Probably Roman soldiers hid their valuable belongings prior to being taken prisoner to prevent them from being taken by the enemies. Thus isolated, even larger wallets could be more easily overlooked than at the Oberesch site, where immediately after the battle many such finds would be lying. But there, leather purses with coins, for example, were still linked to the bodies and therefore more obvious to the looters.

At many sites west of the Oberesch site, at the slope of the mountain, there is further evidence that Roman soldiers aimed to escape and became involved in succeeding skirmishes. Even the 150 Roman coins and pieces of military equipment found in the area of a Germanic settlement circa 2 km west of the Oberesch site (Kalkriese-Dröge, Fig. 1, No. 2), point to combats and post-battle looting, not to booty transported to the settlement from another place in the battle area. The finds were dispersed across the settlement and beyond. Similar to the Oberesch site, the objects were small or fragmentary, and not selected items as can be expected, when booty was stored, for example, in a craftsman's or merchant's depot.

The notion of post-battle loot that was transported to the settlement at Kalkriese-Dröge can likely be refuted by the observation that there are very few Roman finds in nearby settlements, though any booty would presumably have been distributed evenly amongst the local population. However, the contrasting numbers of Roman finds east versus west of the Oberesch site, including those from the indigenous settlements, can be better explained with the development of the battle. The losses of the Roman army were less severe in the east than in the west, where the disorder among the troops would have been much bigger.

The complexity of the processes influencing the spatial distribution of archaeological artifacts on the battlefield can also be deduced from further observations. The numerous brooches and coins at Kalkriese-Dröge suggest that not only last combats took place here but also that soldiers managed to get to this area with their field packs intact. This may point to the strategy of the Germanic tribes of having some Roman units pass the bottleneck in an early phase of the fightings, before starting first attacks at different places at the same time. Perhaps the finds from the Dröge site indicate the overlay of two phases of the battle. Moreover, at Dröge, there were only a few finds of military equipment necessary for fighting. Fragments of shields, for example, are lacking completely. This might suggest that the Germanic warriors made more Roman war prisoners towards the end of the battle, once they felt more secure in their likelihood of being victorious. These prisoners of war who were valuable booty, too, might then be taken to the Oberesch site to be gathered in one place, and would have had to carry parts of their equipment there.

Naturally, some objects were lost even when the Germanic victors transported the booty to their tribal territories, and this is shown via fragments of silver sheets in the northwest of the battle ground that may have been scrapped before at other places such as the Oberesch site. The various observations concerning the spatial distribution of archaeological finds at Kalkriese demonstrate that the number of finds in one section of the conflict landscape does not necessarily allow to draw conclusions on the intensity of the fightings in this zone.

International Perspectives

The evaluation of the find distribution at Kalkriese has shown the extent to which the post-battle processes, especially the lootings and the handling of the booty and the fallen soldiers, affect the archaeological records of historical battlefields. Although it is not always possible to decide to what extent the various types of behavior took effect, the latest source-critical approach enables the development of methodological foundations for the comparatively novel discipline of battlefield archaeology.

One should bear in mind, however, that it was the cultural and historical framework that had a significant impact on the archaeological record on the battleground of Kalkriese. On one hand, an extensive army that was heavily equipped with metal and accompanied by a large baggage train was largely annihilated, on the other hand, the victors were not interested in the original function and purpose of all of the acquired loot. The resulting scrapping at the battleground in favor of acquiring metal as raw material has substantially enlarged the archaeological material at the battlefield. Oftentimes, however, the remains found on sites of military combat consist mainly of ammunition that is too small and worthless to be collected during the looting. Therefore, the research results of the battlefield at Kalkriese are not automatically transferable to other battlegrounds.

Future Directions

Similar phenomena of transmission that are like Kalkriese are primarily to be expected for both ancient and more recent sites of military conflict if they display patterns of asymmetrical warfare and particular interest towards military equipment as spoils. Future investigations not only at ancient battle sites but also, for example, at sites of

American-Indian Wars dating from the seventeenth to the nineteenth century may deliver insights which will help to successfully develop the investigation of landscapes of conflict as a field of research within the discipline of archaeology.

Archaeology of Mining

Linda R. Gosner
Department of Classical Studies, Society of Fellows, University of Michigan,
Ann Arbor, MI, USA

Introduction

The extraction and processing of metals and other minerals have played a significant role in economic, political, and social developments across the globe from early in prehistory to the present day. Processes of mining and metallurgy have left a number of material traces in the archaeological record, from mines themselves, to metallurgical slag and other waste, to finished metal objects, and to traces of environmental pollution. Likewise, mining landscapes often preserve other features related to mining labor and the economy, including settlements for housing laborers as well as roads and railroads for shipping. As such, mining has been examined from a variety of different archaeological perspectives and methods. The archaeology of mining, while in no way a cohesive subdiscipline, plays an important role in industrial archaeology and archaeometallurgy; in period-specific subfields including historical archaeology, prehistory, and classical archaeology; as well as in various area studies fields. It shares much in common with studies of other extractive industries such as quarrying stone or drilling for oil. Studies of mining technologies, landscapes, and communities have also contributed to wider conversations in archaeology about labor history, the history of technology, human-environment interaction, economic history, imperialism and colonialism, and conservation and preservation, among other varied topics. This entry provides a broad overview of the archaeology of mining. It begins by outlining the historical trajectory of studies of mining and metallurgy in archaeology from the pre-modern period to the present. It then discusses current trends and debates in the archaeology of mining relating to scientific methods, social approaches, as well as the conservation and preservation of mining heritage. Finally, it discusses international trends and future directions in research on mining. Given the disparate and diverse scholarship that intersects with and contributes to the archaeology of mining, selected examples provided are intended to be illustrative rather than comprehensive.

Definition

The archaeology of mining is a diverse topic studied from a number of different theoretical and methodological perspectives within archaeology. It involves the study of the material remains of mining from prehistory to the present, both before and after the Industrial Revolution. Such material remains include a wide variety of landscape features, artifacts, buildings, and infrastructure associated with mining. Most archaeological studies of mining in both ancient and contemporary contexts until relatively recently focused on uncovering evidence for the technologies surrounding the extraction and processing of ores: mines, tools, and equipment. The structure of mines themselves varies by period, geography, geology, type of ores extracted, and techniques used to extract them. Mines generally fall into two basic categories: underground mines and

Archaeology of Mining, Fig. 1 Remains of stairs leading between two galleries in Três Minas (Vila Pouca de Aguiar), Portugal, a large Roman gold mining complex. Red paint indicates places where modern prospecting has been carried out. (Photo by author)

opencast mines. Underground or deep-vein mines consist of subterranean tunnels including vertical shafts, horizontal galleries, and horizontal adits (horizontal passages that can be used for accessing an ore body or for drainage) that penetrate below the surface of the ground (Fig. 1). Underground mines are normally opened to either extract hard minerals containing metal ores or to extract soft minerals such as coal or salt. Opencast, open-pit, or opencut mines are created when large a quantity of material is extracted from the surface, thereby creating a pit, depression, or large hole. Contemporary open-pit mines can be recognized for their distinctive benches or stepped platforms that are cut to create access to lower levels (Fig. 2), while ancient examples are typically less regular and smaller in size. Opencast mines are used when ores are found relatively close to the surface and/or when the earth is not stable enough for underground mining. These methods have sometimes been used simultaneously, or one after another in different phases of mining in the same area. The development of contemporary opencast mining, which involves the removal of all the material inside the pit and more efficient processing techniques, has allowed the extraction of low-grade ores to become profitable. It is for this reason that ancient underground mines are sometimes reopened to exploit low-grade ores using opencast mining techniques. Aside from evidence for these various techniques of extraction, mining landscapes often contain evidence of sorting, processing, and refining ores. These include crushing platforms and stones, smelting furnaces, and slag heaps. A wide range of tools and other materials are often found in association with mines, especially in abandoned underground mines where anaerobic environments favor the preservation of organic materials such as clothing, baskets, and wooden equipment. The preservation of many components of mining landscapes varies widely across time and space. Because mining is an inherently destructive activity, older evidence of exploitation is often obliterated in the process of later mining activity. The conservation of mining heritage has received increasing attention with the spread of amateur and academic interest in industrial archaeology and as topics such as rural landscapes and labor history have become more prominent in archaeology.

As research questions in the archaeology of mining have expanded to address more than the technologies of mining, the range of material evidence employed for study has also expanded. Mines are now more often contextualized in their wider landscapes through the study of infrastructure such as railroads, roads, and ports. A desire to understand the organization of labor, the lived experience of miners, and topics such as community formation and identity at mining sites has also led archaeologists to study mining settlements, including houses, cemeteries, churches, stores, and other common spaces. Finally, increased interest in pollution and human health has also incited archaeologists to employ scientific techniques to study the environmental impacts of mining in the past and present.

Historical Background

Pre-modern Interest in Mining

There has long been an interest in exploring human engagement with metal-rich landscapes and a range of material and written sources from across the ancient world document mining technologies, mining landscapes, and labor practices. In ancient Egypt, for instance, a map of an ancient mining landscape in the Eastern Desert is depicted on a papyrus dating to the mid-twelfth century BCE (Fig. 3). This topographical map was produced during the reign of Ramesses IV in the 20th dynasty, apparently to map the locations of gold mines and sandstone quarries in Wadi Hammamat for royal mining expeditions (Shaw 1994: 111). Depictions of metallurgy are also known from Egypt, for instance, in the 18th dynasty (c. 1550–1292 BCE) tomb of vizier Rekhmire in Thebes (TT100) (Ogden 2000: 150).

Observations about mining and metallurgy also abound in Greek and Roman written sources (for a compilation, see Humphrey et al. 1998: 173–233). Of particular significance is Pliny the Elder's first century CE encyclopedic compendium, *Historia Naturalis*, which includes two full books about the history of metals, where the author details the state of Roman knowledge about gold, silver, copper, mercury, lead, tin, iron, and a number of alloys (*Natural History* 33–34). Pliny's elaborate description of gold mining in northwest Spain (*Natural History* 33.66–78) closely matches archaeological evidence for gold mining at the UNESCO World Heritage Site of Las Médulas (El Bierzo, León, Spain) (Fig. 4). Both Greek and Roman authors described the difficulties of laboring in mines (e.g., Diodorus, *History* 3.12-13.1, 5.36–38; Xenophon, *Ways and Means* 4.14–17), but archaeological investigations relating to mining

labor have not become widespread until more recently. While visual and textual evidence certainly appear in other ancient cultural traditions, classical texts are emphasized here for the role they came to play in later mining history.

Mining is also recorded in maps and handbooks from more recent history, many of which were used by mining engineers and distributed widely thanks to the invention of printing. Perhaps most significant to the history of mining is Georgius Agricola's *De Re Metallica*, published in 1556 (Fig. 5). This is a twelve-book treatise illustrated with woodcuts that outlines in great detail the methods for mining, refining, and smelting metals. Printed in Latin as well as in German and Italian translations, the book was influential throughout Europe as a source for understanding mining technologies of the era. It also served to keep the memory of ancient mining alive with frequent references to classical authors and their descriptions of mining. In 1912, former US president Herbert Hoover and his wife Lou Henry Hoover produced an English translation with annotations that has been reprinted multiple times and is still well-regarded today (Hoover and Hoover 1950).

While these are but a few examples of extant visual and written sources from before 1600, they attest to the long-standing human interest in mining landscapes and technologies across various pre-modern cultures and time periods. While these sources certainly predate a contemporary "archaeology of mining," they are useful in interpreting the archaeological evidence for mining that has survived from the ancient and more recent past as well as in understanding engagements of people with mining landscapes over the *longue durée*.

Mining Scholarship in the Nineteenth and Twentieth Centuries

Modern scholarship on the archaeology of mining has, until recent decades, focused primarily on the technologies surrounding the processes of extracting, refining, and smelting metals. Many of the earliest scholars writing on what might be classified anachronistically as the "archaeology of mining" were themselves mining engineers rather

Archaeology of Mining, Fig. 5 Woodcut from Georgius Agricola's *De Re Metallica* (1556) depicting miners at work. (Public Domain, https://commons.wikimedia.org/w/index.php?curid=400140)

than trained archaeologists. Through their occupations, they had access to mining sites with deep histories of exploitation. Mining landscapes were rarely of major interest to archaeologists in the nineteenth and twentieth centuries, who instead were focused primarily on urban places and elite spaces. Significantly, mining engineers also had the technical expertise necessary to undertake rigorous analysis of the ancient archaeological evidence that they encountered in the course of contemporary mining operations. Often, these were people educated in the classical tradition according to the standards of their day (Dietler 2010: 27–42), so they could read the work of Agricola and Pliny the Elder. Herbert Hoover, for instance, was trained as a mining engineer, while his wife was a geologist and scholar of Latin. They had the ideal combined skillsets to produce a clear translation of *De Re Metallica* from the Latin, complete with footnotes referencing and describing relevant Latin and Greek authors to whom Agricola frequently referred.

Anglophone scholarship on mining from the nineteenth and twentieth centuries often focused on the history of the development of mining technology in specific locales or on the place of mining in world history. In the former category, for instance, is Nash's history of the Riotinto mines in southwest Spain (1904). In the latter is the work of Thomas Arthur Rickard (1864–1953). Born in Italy, Rickard came from a family of English mining engineers and worked in the industry for most of his career in the United States. Although he was a prolific scholar, he is most famous for his seminal two-volume work, *Man: and Metals: A History of Mining in Relation to the Development of Civilization* (1932). The book focused on the deep history of mining in the Old World and its relationship with the development of human culture. In this and other publications, his attention to both classical written sources and archaeological findings from mines is notable. Scholarship from the nineteenth and the early twentieth centuries, as well as the history of amateur collection in and around modern mines, ensured the survival of material evidence for mining at a time when there was not a great deal of interest in the subject on the part of archaeologists.

Archaeological interest in ancient mining, at least in Europe, began to arise after Rickard's initial work. The first major synthesis of mining sites in the Roman Empire was Englishman Oliver Davies' *Roman Mines in Europe* (1935). He produced maps and wrote descriptions of mines based on personal visits to mining sites. He lamented: "the evidence for ancient mines is in all cases poor, and archaeologists must not demand so strict a standard as in other branches" (1935: preface), a quote which aptly demonstrates the negative archaeological perspective on mining sites at the time. Later volumes contributed to deeper understanding of mines in antiquity, especially during the classical period. John F. Healy's *Mining and Metallurgy in the Greek and Roman World* (1978), for instance, has remained an important resource on mining itself as well as issues surrounding the administration and labor of mining in the classical Mediterranean. Likewise, Robert Shepherd's *Ancient Mining* (1993) traces developments in mining from prehistory to the later Roman Empire and includes information about labor and administration.

Studies of the archaeology of mining in prehistory also began to proliferate in the mid-twentieth century, many of which maintained a focus on the technologies surrounding mining and metallurgy. Significant volumes with a primarily technological focus include R.F. Tylecote's *A History of Metallurgy* (1976) and *The Early History of Metallurgy in Europe* (1987) as well as Paul T. Craddock's *Early Metal Mining and Production* (1995). Writing more specifically about the United Kingdom, Tylecote also published *Metallurgy in Archaeology: A Prehistory of Metallurgy in the British Isles* (1962) and, later, *The Prehistory of Metallurgy in the British Isles* (1986). Aside from these studies focused primarily on European mining history, other archaeological investigations have also been heavily focused on the technologies of mining and metallurgy. Beginning around the 1970s, a strong tradition of scholarship emerged that made use of scientific methods and techniques to study mining technologies. This was influenced both by the

predominant processual paradigm as well as advancements in the application and use of archaeometric techniques.

In addition to work on the archaeology of mining in ancient times, the field of industrial archaeology began to take shape from the 1950s as interest increased in preserving industrial heritage, inventorying industrial sites, and studying industrial technologies from an academic perspective. This field, which traces its origin to the United Kingdom, includes the study of mines dating to after the Industrial Revolution, as well as a variety of other sites with industrial buildings and structures such as mills and factories (Palmer and Neaverson 1998). Because industrialization took place earlier in some places than others, material remains considered industrial heritage can be as early as the sixteenth century but are often much more recent. Early work in industrial archaeology has been criticized for its focus on technology and conservation at the expense of other relevant topics, but more recent work has begun to contextualize industrial heritage in the wider discipline of historical archaeology. Mining heritage is not considered alone and solely for its technological value but as part of the wider industrial landscape, including towns, settlements, and supporting infrastructure (e.g., trains, railroad tracks, roads, and power plants).

Key Issues/Current Debates

The scope of the archaeology of mining began to change and grow from the early 1980s in step with theoretical shifts in archaeology – especially the post-processual turn. While previous investigation had been primarily concerned with understanding the technologies and processes surrounding mining itself, archaeologists began to realize increasingly that mining could be used to study a number of social and economic topics. Further, evidence from mining sites could be used to address questions of larger interest in the archaeology about gender, indigenous archaeology, and postcolonial archaeology, among others. Historical archaeologists, perhaps because of the wider range of material and written evidence available to them, were among the first to publish more interpretive, analytical, and holistic investigations of mining landscapes and communities (see especially Hardesty 1988). The conference and subsequent publication of *Social Approaches to an Industrial Past: The Archaeology and Anthropology of Mining* (1998) can be seen as an important turning point for research in the archaeology of mining. The volume brought together archaeologists, ethnohistorians, and anthropologists working in disparate geographical locations and from varied disciplinary backgrounds to discuss the social context of mining from prehistory to the recent past. Significantly, while mining sites from before and after the Industrial Revolution had traditionally been studied separately, the editors made a case for the broad comparison of mining landscapes across time periods and locations. While the "archaeology of mining" will never be a cohesive subdiscipline, the volume has prompted increased interdisciplinary work and cross-regional discussion over the past two decades.

Today, the archaeology of mining is studied under the purview of many divergent disciplines and subdisciplines in the humanities, social sciences, and hard sciences. Mining is also studied unevenly and from varied perspectives in different regions of the world. As in previous centuries, the study of mining as a part of the history of technology continues to play an important role in new research, but discussions about technology are increasingly being enhanced by new methods of inquiry as well as through their incorporation into wider questions about the social and economic significance of mining. Much of the most innovative and/or debated work of the past several decades can be grouped into the following three categories: methodological advancements in archaeometallurgy and geospatial technologies, social approaches, and conservation and preservation.

Methodological Advancements

Advances in archaeometry, geospatial, and digital technologies have enhanced the archaeology of mining and led to new discoveries as well as to changing methods for mapping, documenting,

and conserving mining landscapes and metal artifacts. The increase in the use of scientific techniques in archaeology from the 1970s onward has catalyzed a number of advances in metal provenience studies, in documenting the impacts of mining pollution on a variety of scales, and in better understanding the origins and development of technologies in mining and metallurgy. Geospatial and other digital technologies have, on the other hand, helped with the mapping and recording of mining landscapes, buildings, and other features.

Archaeometallurgy

Archaeometallurgy, the study of the use and production of metals in both prehistoric and historic periods, is a subdiscipline of archaeometry or archaeological science. Key areas of research in archaeometallurgy include the origins and dispersal of metallurgical technology, the reconstruction of metallurgical technologies that have fallen out of use, and the identification of the provenience of objects and ores to their geological origins through chemical and isotopic fingerprinting (Killick and Fenn 2012: 560–561). Some of the commonly used methods for the analysis of ores, metals, and slag include optical microscopy, electron microscopy, X-ray diffraction (XRD), Raman microscopy, portable X-ray fluorescence (p-XRF), energy-dispersive X-ray analysis (EDX), wavelength-dispersive X-ray analysis (WDX), and inductively coupled plasma spectroscopy/spectrometry, among a variety of others (Roberts and Thornton 2014). A multitude of archaeometric and archaeometallurgical studies related to mining technology can be found in the *Journal of Archaeological Science*, the *Journal of Archaeological Science: Reports*, and *Archaeometry*, among others.

For prehistorians, there has been long-standing debate concerning when and where the mining and extractive metallurgy of different ores originated. There have long been questions about the origins and spread of smelting technologies in the Old World and whether smelting was invented on multiple occasions in disparate locales or just once. In the 1960s, for instance, Colin Renfrew argued – against V. Gordon Childe's previous arguments for a single invention of metallurgy – that copper metallurgy was invented on multiple occasions in the ancient Near East, in the Balkans, and in Iberia. The past decades have seen a great deal of local research and global debate on these issues as new archaeological evidence has been found and archaeometric techniques have become more widely used. For instance, in 2009, the *Journal of World Prehistory* produced two special issues on the topic "Modelling Early Metallurgy" (Vols. 3 and 4). These volumes provide outlines of the state of this debate in various places including West, East, and Southern Africa, Thailand, South India, Western Europe, the Eurasian Steppe, Eastern Asia, Iran, the Southern Levant, the Indus Valley, the Eastern Woodlands of North America, and West Mexico. Concerning copper, most scholars now contend that copper metallurgy in Europe spread from east to west, beginning in Southeast Europe in the late 6th millennium BCE and culminating in Britain and Ireland by the mid-3rd millennium BCE. Further, the "virtually synchronous appearance of copper smelting throughout Southwest Asia and Southeast Europe, [shows that] a single central region of invention is far more probable than many parallel independent discoveries" (Roberts et al. 2009: 1012–1014).

Chemical and isotopic fingerprinting – including isotopic analysis of lead, copper, and copper-based alloys – are also major areas of research in archaeometallurgy. In particular, the application of lead isotope analysis to metal objects and ores has increasingly been carried out as a way to pinpoint the provenience of objects and characterize isotopic signatures for various mining districts. Identification of the origin of objects can help not only in the reconstruction of trade networks but also in better understanding the organization of production and its connection to economic systems in past societies. These methods can also be used to reconstruct processes of recycling, mixture, and reuse of metals of diverse origins. In the past decades, lead isotope analysis has shed light on topics such as the production of copper oxhide ingots in Late Bronze Age Cyprus, the origins and distribution of Roman lead ingots in the Mediterranean, and the

mixing of metals in coins, pipes, and archaeological objects from many times and places. Isotopic analyses have allowed researchers to trace the impacts of mining pollution and environmental degradation on local, regional, and even global scales. Most famously, Sungmin Hong and colleagues traced hemispheric lead pollution on a global scale by conducting lead isotope analysis on ice cores from Greenland. In doing so, they showed how mining in the classical Mediterranean contributed to levels of hemispheric pollution not observed again until after the Industrial Revolution (Hong et al. 1994). This research inspired a number of subsequent studies that helped pinpoint the geographic origins of pollution, the impacts of pollution on local plants and animals in mining districts, and the consequences of pollution for human health past and present. It has recently been reproduced with greater accuracy, allowing scholars to pinpoint fluctuations in pollution levels to specific economic and historical events (McConnell et al. 2018).

Geospatial and Digital Technologies

Advances in geospatial technologies have also expanded the ways in which mining landscapes can be documented and studied. Increasingly, archaeologists are using laser scanning, digital photogrammetry, geographic information systems (GIS), and other digital tools to map mining landscapes and features within them. These technologies have applications for making and documenting new discoveries. In addition, they are useful in monitoring changes in landscapes or the deterioration of archaeological sites for the purposes of environmental and heritage conservation and preservation. In one recent study of the Eria Valley in northwest Spain, archaeologists employed airborne LiDAR and aerial photography to create high-resolution digital terrain models of a Roman-era gold mining landscape. LiDAR, or Light Detection and Ranging, is remote sensing method that produces high-resolution digital surface models and topographic maps. Because of dense vegetation across the region, it had previously been difficult to determine the extent of hydraulic gold mining features such as trenches, canals, and mining deposits. The application of these technologies, and especially of LiDAR, brought to light these features and helped to document the extent of ancient gold mining in the region using GIS (Fig. 6; Fernández-Lozano et al. 2015). This technique is increasingly used to study ancient mining landscapes elsewhere. New technology is also employed for recording buildings and features of particular mining sites. A recent study of the nineteenth and twentieth century Our Lady of Montserrat mine in Cartagena-La Unión, Andalucía (Spain) employed laser scanning on a smaller scale. Using terrestrial laser scanning and airborne LiDAR textured with photographs, archaeologists created a textured digital model of the boiler room and chimney associated with the mine (García-León et al. 2017). The images produced serve to record the state of preservation of the building for the purposes of monitoring heritage preservation, and they can be used as accurate and realistic models of the site for both specialized and public uses. Outside of archaeology, LiDAR and other technologies are also sometimes employed in active mining projects for recording changes to landscapes and coastlines in order to monitor environmental impact and legal compliance, among other things (e.g., Kerfoot et al. 2014).

Social Approaches

While most archaeological studies of mining and metallurgy before the 1980s focused primarily on the locations of mines and the technologies used to extract and process metals, the rise of post-processual approaches in archaeology has led archaeologists to expand the range of research in the archaeology of mining to address debates about a broad range of social, economic, and ideological questions. Some of this has been the result of the increased integration of the archaeology of mining into other subdisciplines within archaeology such as historical archaeology and classical archaeology. Questions have also evolved with the increased integration of archaeological approaches to mining and ethnographic or ethnoarchaeological studies of contemporary mining landscapes and communities. It is

Archaeology of Mining, Fig. 6 (**a**) Digital elevation model of gold mining features, including canals and reservoirs, in the Eria Valley obtained from LiDAR data and (**b**) archaeologists, interpretation of the same landscape from aerial orthoimage and LiDAR data. (Fernández-Lozano et al. 2015, used with permission from Elsevier)

impossible to cover the breadth of this research, but I will highlight several interesting directions that mining research has taken both in and outside of archaeology.

Importantly, scholarship about mining technology itself has taken a more social turn, as archaeologists have increasingly recognized the social aspects of technological practice. Bryan Pfaffenberger, for instance, has advocated using the concept of the *chaîne operatoire* to study mining. This concept emphasizes the role of learned practices and social interactions in the

execution of technical processes and has often been applied to case studies in the production of lithics and ceramics (Pfaffenberger 1998). Thus, even when studies of mining remain technologically focused, there is increased discussion about the transmission of knowledge and the organization of labor in technical processes.

The broad topics of mining labor, work, and community have also become more prominent in recent decades. In 1985, Ricardo Godoy commented, "Despite his antiquity, the miner, like Geertz's peasant, was recently discovered by anthropologists. . .If interest in mining came late, systematic studies of mining have yet to arrive" (1985: 199). Since the publication of this article in the *Annual Review of Anthropology*, which was one of the first articles to present the potential contributions of mining to studies about labor history to a wide audience of anthropologists, studies about the social and economic organization of mining labor have proliferated in anthropological archaeology and cultural anthropology. Overlapping with research in the archaeology of women and gender, archaeologists have examined the roles that women and children have played in mining labor, household production, and subsidiary industries in mining communities. Research has also examined the role of other overlooked groups in mining, including slave laborers, corvée laborers, immigrants, itinerant laborers, and indigenous groups. Increasingly, archaeologists are interested not just in the organization of labor and the identification of laborers but in the lived experiences of those who formed mining communities.

This diverse research on labor has taken a wide variety of theoretical and methodological approaches in different regions and periods, especially because of disparities in the kinds of material available to study these topics. In historical archaeology in the United States, for instance, scholars have often adopted Marxist approaches to conceptualize mining labor practices. Historical archaeology has also benefitted from the existence of company records (financial, administrative, and medical), newspapers, personal journals, as well as photographs and oral histories that record details about life in mining communities not available for earlier periods. At the twentieth-century American coal mine of Ludlow, Colorado, for instance, a labor strike in 1914 resulted in the brutal massacre of miners and their families as well as the destruction of the town by the Colorado National Guard (Fig. 7). The "Archaeology of the Colorado Coalfield War Project," directed by Randall McGuire, Dean Saitta, and Phillip Duke, has been able to study the vivid photographs and other documentary records alongside the burned remains of the town, revealing more about life at the mine and how the massacre unfolded (McGuire 2004).

The role of the extractive industries, and especially mining, in imperial and colonial encounters has also become a topic of increasing interest to archaeologists, anthropologists, and historians. As Killick and Fenn note, "Because rich deposits of the scarcer metals are rare, and rarely coincide in space and time with the regions of greatest demand for them, the quest for metals has been a major driver of exploration, long-distance trade, colonization, and imperialism" (2012: 560). Research on the relationship between mining and colonialism has been carried out in various Mediterranean regions that were once provinces of the Roman Empire (especially Spain and Romania) as well as in more contemporary colonial mining landscapes including Australia and New Zealand. Archaeologists working in colonial Latin America have produced some of the most notable scholarship in this vein. Nicholas Robins, for instance, examined the relationship between Spanish colonialism and mining in the Andes in his book, *Mercury, Mining, and Empire: The Human and Ecological Cost of Colonial Silver Mining in the Andes* (2011). In his interdisciplinary study, Robins combined historical archival research with environmental data to study the use of mercury in the amalgamation process for silver after it was introduced by the Spanish in the late 1500s, revealing the adverse impacts that mercury pollution had on human health and the environment.

Drawing on phenomenological approaches to landscapes and materials, scholars have also become increasingly interested in the ritual and symbolic significance of mines, minerals, and

Archaeology of Mining, Fig. 7 Historic photograph of the aftermath of the Ludlow massacre showing the burned ruins of the mining houses at Ludlow Colony in 1914. (George Grantham Bain Collection of the Library of Congress, Public Domain)

mining landscapes. Notable studies that comment on these topics include a recent edited volume on mining and quarrying in the ancient Andes (Tripcevich and Vaughn 2013), Knapp's discussion of ideational mining landscapes in prehistoric Cyprus (Knapp 1999), and Boivin and Owoc's edited volume on cultural perceptions of the mineral world (2004).

Finally, modern global debates concerning the economics and politics of mining, local environments, and indigenous communities can also be seen reflected back in studies of mining and in the profile of mining in scholarly publications both in and outside of archaeology. Following on Godoy's influential work, Chris Ballard and Glenn Banks wrote an article about the role of the anthropologist in engaging with local communities and large corporations in post-1980s large-scale hard-rock mining in the Asia-Pacific region (2003). Their work showed the critical role that anthropology and ethnography can play in understanding conflicts over natural resources. It also outlined practices for ethical engagement with the various stakeholders in contemporary mining ventures. More recently, Routledge initiated a publication series called "Routledge Studies in the Extractive Industries and Sustainable Development" in 2016, which already has eight volumes related to mining. A new journal, *The Extractive Industries and Society*, was formed in 2014 for the dissemination of "in depth analysis of the socio-economic and environmental impacts of mining and oil and gas production on societies, both past and present" (https://www.journals.elsevier.com/the-extractive-industries-and-society). The presence of such publications demonstrates that mining studies are no longer confined only to specialized engineering journals but have become more integrated into other research in anthropology and sustainability, among other disciplines.

Conservation and Preservation of Mining Heritage

The conservation and preservation of metal artifacts – including coins, jewelry, and vessels –

have long been important activities on archaeological excavations and in museums around the world. The conservation and preservation of mining heritage sites across the world, on the other hand, are more recent developments in archaeological practice and ones that are implemented in a variety of different ways by region and by country. Some places still have few or no legal protections in place for mining heritage. Nevertheless, worldwide attention to the preservation of mining sites has grown as a result of two primary factors. The first are the changing research foci of archaeologists within academia. Increasingly, archaeologists are studying the everyday lives of non-elites, as well as nonurban landscapes, recognizing the significance of people and places outside of upper-class, urban environments. The archaeology of mines – including research on industrial landscapes, mining labor, and mining settlements – has gained momentum with these shifting research agendas. Efforts to preserve mining heritage have increased with the elevated scholarly interest in mining. Secondly, the preservation of mining sites can also be attributed to changing societal attitudes toward industrial heritage in many countries: mines and mining towns are now often considered places of historical interest, deserving of legal protections and preservation. This can be observed in recent legislation in many countries that has given mining landscapes additional legal protections as well as the emergence of national and international societies and interest groups dedicated to the study and conservation of industrial heritage. Mines and their settlements, further, are more often being preserved, conserved, and repurposed for tourism or other secondary, adaptive reuses.

The International Committee for the Conservation of the Industrial Heritage (TICCIH) is the worldwide organization for the promotion, conservation, documentation, and investigation of industrial heritage. While both individuals and institutions can become members of TICCIH, its activities are primarily carried out through national organizations in 40 member countries. These include, for instance, the Society for Industrial Archaeology (United States), the Association for Industrial Archaeology (United Kingdom), Associazione Italiana per il Patrimonio Archeologico Industriale (Italy), and the Associação Portuguesa para o Património Industrial (Portugal). TICCIH is the consultant to the International Council on Monuments and Sites (ICOMOS), which in turn advises UNESCO on industrial heritage sites to be added to the World Heritage List (TICCIH 2017). Many industrial mining sites or complexes have indeed been designated as World Heritage such as Sewell Mining Town (Chile), the Cornwall and West Devon Mining Landscape (United Kingdom) (Fig. 8), Zollverein Coal Mine Industrial Complex in Essen (Germany), Nord-Pas de Calais Mining Basin (France), and Sites of Japan's Meiji Industrial Revolution: Iron and Steel, Shipbuilding and Coal Mining, among others (UNESCO 2017a).

TICCIH has a specific focus on heritage dating to periods during and after the Industrial Revolution. There is no similar international organization centered around ancient or preindustrial mining heritage sites, though interest groups and societies do exist in some countries. In the United States, for instance, the Prehistoric Quarries and Early Mines Interest Group is a subgroup of the Society for American Archaeology. In the United Kingdom, the Historical Metallurgical Society Ltd. advocates the study of metals and conservation of metallurgical sites from prehistory to the present. Various ancient mining sites do have designations as UNESCO World Heritage Sites, such as Las Médulas in northwest Spain (Fig. 4) and the Neolithic flint mines at Spiennes in Belgium. Other preindustrial sites from later periods include the Spanish colonial mining towns in South America, including the city of Potosí in Bolivia and the historic town of Ouro Preto in Brazil. Certainly, many World Heritage mining sites have evidence of exploitation from ancient to more recent times, spanning the pre-/post-Industrial Revolution divide. The Mining Area of the Great Copper Mountain in Falun (Sweden), Iwami Ginzan Silver Mine and its Cultural Landscape (Japan), Heritage of Mercury: Almadén (Spain) and Idrija (Slovenia), and the city of Potosí are just a few examples (UNESCO 2017a).

Archaeology of Mining, Fig. 8 The remains of a Cornish engine house at the tin mines in the St. Just Mining District, part of the "Cornwall and West Devon Mining Landscape," a UNESCO World Heritage Site. (Photo by Will Wallis, Public Domain)

The issues of modern exploitation of earlier mining landscapes are also one with which lawmakers and cultural heritage specialists must contend. Beginning in 1998, UNESCO has reiterated on a number of occasions that mineral, oil, and gas exploration and exploitation should not be undertaken at World Heritage Sites (UNESCO 2017b). This serves as an additional protection for both ancient and contemporary World Heritage mining sites where mining could be reinitiated. Its impact on contemporary mining can be observed in the ongoing debate about whether to reinitiate mining at the site of Roşia Montană (Romania), the site of well-preserved subterranean Roman gold mines of the second and third centuries CE. A Canadian company, Gabriel Enterprises, together with the Romanian state-owned company Minvest Deva hoped to open Europe's largest gold mines in the area using cyanide-based open-pit mining. After years of protests by environmentalists and heritage specialists both locally and internationally, Roşia Montană was placed on the tentative list for consideration for World Heritage in February 2016 (Fig. 9). This will effectively halt plans to reopen mines in the area if and when the proposal is accepted (Rosia Montana 2016).

While it is impossible to cover issues and policies surrounding mining heritage from all national perspectives, I will provide a few examples that illustrate shifting attitudes toward mining heritage and the variety of solutions for its preservation at the national level. In the United States, the number of mining sites being recorded as cultural heritage sites increased as a result of the inventories produced following the Historic Preservation Act of 1966 and its subsequent amendment in 1980, enacted to preserve historical and archaeological sites broadly defined. This law provides a legal mandate to preserve mining areas classified as archaeological sites. However, the application of the law has historically been complicated by the General Mining Law of 1872, which allows all US citizens over 18 years old to locate and make claim to valuable minerals on public lands. Nevertheless, this legislation has provided legal protection for both mines and their associated settlements in many parts of the United States, as well as incentive for local communities to develop tourism dedicated to these places (Bakken 2008; Hardesty 1988: 105–107).

Bisbee, Arizona, a mining town that grew up to support the Copper Queen Mine in southern Arizona's Cochise County, illustrates these phenomena well. There, copper, gold, silver, and turquoise were mined beginning in 1880. Mining activity began to wane across southern Arizona by

Archaeology of Mining, Fig. 9 Protests against the reopening of gold mines at Roșia Montană in Timisoara, Romania, on September 22, 2013. The banner bears the logo of the grassroots Save Roșia Montană campaign and reads "Now or Never" in Romanian. (Photo by Ady777, CC-BY-SA-3.0)

the 1950s, and mining operations in Bisbee itself were officially halted in 1975. At that time, the city began its transformation into both a center for tourism related to its mining heritage and a quirky refuge for artists. Guided tours of the abandoned Copper Queen Mine began in 1976, with support of Mayor Chuck Eads and a federal grant from the Economic Development Administration. Multiple sites in the town have been classified on the National Register of Historic Places beginning with the Bisbee Historic District in 1980. Some of these are used for mining tourism, such as the Phelps Dodge General Office Building (classified in 1983), which was formerly the headquarters of the Phelps Dodge mining company and now serves as the Bisbee Mining & Historical Museum. The exodus of mining labor from the town also provided affordable real estate, which has been slowly purchased by artists and hippies, who have likewise contributed to the gentrification of Bisbee's historic districts and the preservation of the town in general (Fig. 10; Copper Queen Mine 2017).

Similar phenomena can be observed in Europe, where industrial heritage has been increasingly recognized as an economic resource in the development of tourism and to promote economic growth in towns where industrial centers have been abandoned. In Spain, for instance, the Plan Nacional de Patrimonio Industrial (PNPI) of 2001, took inspiration from legislative trends in Germany, the United Kingdom, Belgium, and elsewhere in Europe (Álvarez Areces 2010). Significantly, the law's definition of industrial heritage is inextricably linked to the Industrial Revolution and the mechanization of industrial technologies, and, as a result, the only mining sites that are included for protection date to the mid-eighteenth century and later. This definition has created a conceptual, and indeed practical, separation between ancient and contemporary mining sites. When preindustrial mining sites are protected, it is under a different designation: they are categorized as "Bienes de Interés Cultural" (goods of cultural interest).

While situations such as this complicate the business of protecting and presenting multilayered, diachronic landscapes with long histories of mining, some specific sites have come up with local solutions. For instance, the Riotinto mines in the Iberian Pyrite Belt (Huelva, Andalucía, Spain) have a history of mining dating back at least 5000 years. As a result, the area is replete with both ancient archaeological traces of mining as well as large-scale opencast contemporary mines. The area is categorized as both a Bien de Interés Cultural (since 2012) and is on the PNPI list of industrial heritage. It has been mobilized for tourism as the Parque Minero de Riotinto, where tourists can visit various parts of the nineteenth century British mining town, its historic railroad, and the opencast copper mines.

Archaeology of Mining, Fig. 10 Historic mining town of Bisbee, Arizona, in February 2010. (Photo by Alan Stark)

Many of the early archaeological traces of mining were destroyed in the processes of later mining operations and cannot be visited. However, the long history of mining is presented in the museum, which is located in the building that formerly served as the hospital for the Río Tinto Company Limited in the early 1900s. There, visitors can view prehistoric and Roman artifacts recovered both by archaeologists in recent excavations and by miners in the course of contemporary opencast mining operations.

International Perspectives

As the previous section on mining heritage suggests, attention to the study and preservation of mining heritage varies widely from region to region and period to period. Industrial archaeology, including the archaeology of mining from after the Industrial Revolution as a subset of this subdiscipline, is a more cohesive and prominent field of study on an international scale than the archaeology of mining from earlier periods. While industrial archaeology originated in Britain in the 1950s, it has since become a robust field in many parts of the world, especially in Western Europe and the United States. The journal *World Archaeology* devoted an issue to the topic in 1983 (Vol. 15, No. 2), indicating that it was growing in significance enough to be the focus of a major journal with international scope. The participation of local societies from across the globe in the International Committee for the Conservation of Industrial Heritage is a further attestation of the international significance of industrial archaeology and attention to the preservation of mining heritage. Excellent regional analyses of historical mining archaeology exist for varied regions (e.g., White 2017 on the United States), and there appears to be healthy communication across regions among scholars engaging with mining in contemporary periods.

The study of mining in earlier periods is not nearly as unified, owing to the broad geographic and chronological scope of ancient mining and the distribution of scholars interested in such evidence across various disciplines and academic departments. Some significant centers include the Institute for Archaeo-Metallurgical Studies at University College London and the Deutsches Bergbau-Museum in Bochum, Germany. Studies

of preindustrial mining are often buried in the pages of local or regional journals that are not distributed widely on an international level. Aside from the limited distribution of such publications, language barriers also restrict international readership, communication, and collaboration. This entry has focused more heavily on the Mediterranean, Middle East, United States, and Spanish-speaking regions than it has on Central or East Asia or Africa because of my own language training, American nationality, and research experience. While it is not possible to review the literature on ancient mining from all regions, many parts of the world have benefitted from prolonged studies of mining at the local, reginal, or national level. Regions for which scholarship is more widely available in Europe and the Middle East include the Iberian Peninsula (especially Spain), the Eastern Desert in Egypt and Sudan, and Wadi Faynan in Jordan, among others. In Latin America, mining has often been studied as a part of wider research about Spanish and Portuguese colonialism, including in Mexico, Peru, Bolivia, and Brazil (Brown 2012). I direct the reader to scholarship in the bibliography and further reading sections for more international perspectives.

Future Directions

The archaeology of mining will continue to expand and evolve in the twenty-first century. This can be attributed to increased interest in the topic from a variety of academic perspectives (both theoretical and methodological) and to the growing involvement of archaeologists in cultural heritage preservation and environmental advocacy. Ever-evolving scientific methods for studying topics ranging from pollution, to metal object provenience, to human health will continue to aid in new research in the archaeology of mining. Further, research into the aspects of past mining beyond technology will continue to expand, increasing intersections between the archaeology of mining and broad areas of interest in archaeology such as religion, migration, empire, and gender, among others. Finally, conflicts between modern mining projects, cultural heritage, and environmental sustainability interests, such as that described at Roşia Montană, will continue to arise as nations and corporations expand into new territories in search of mineral resources or seek to use more destructive methods of mining. Archaeologists knowledgeable about mining are well poised to play a central role in the study and preservation of ancient and industrial mining landscapes as well as of archaeological sites located in areas of interest for contemporary mining prospection. Increasing archaeological collaboration with indigenous groups and environmental advocates will also pave the way for future work in these areas.

These trends indicate that the archaeology of mining will continue to be a topic studied from a diverse range of theoretical, geographical, chronological, and methodological perspectives. Books such as *Social Approaches to an Industrial Past: The Archaeology and Anthropology of Mining* (1998) paved the way for more interdisciplinary collaboration in the archaeology and anthropology of mining and research on shared thematic interests. There has indeed been more of this type of research in the past 20 years, as indicated, for instance, by the founding of the journal *The Extractive Industries and Society* in 2014 and the inclusion of several sessions dedicated to mining in the 2018 International Congress of Classical Archaeology. Nevertheless, the archaeology of mining is not likely to become a more coherent field as a result of the vast differences in the scale, organization, and technologies employed in various times and places across the globe. Instead, it will continue to be a topic studied under the purview of a multitude of other topics and specialties in archaeology.

State of Knowledge and Current Debates

Introduction

This essay addresses the archaeology of a section of the South American highlands, known in Spanish as *Puna* or *Altiplano*, which extends from Peru to Northwest Argentina. Here we will focus in the portion that encompasses part of Northwestern Argentina (see Fig. 1). This sectioning is partly based on the history of ethnohistorical and archaeological research, as well as on traditional geographical divisions. Although the northern part of the Argentine Puna had deep connections with the Bolivian Altiplano and the limits that now divide the national territories were only established in the nineteenth century, there are differences in the periodification and chronological frameworks currently used in both sides of the border. Nonetheless, there is always a subjective judgment in making a geographic cut of such a vast area.

Although it is impossible to be exhaustive in the synthesis of the archaeology developed and

Archaeology of Northwestern Argentinean Puna, Fig. 1 Map of the areas mentioned in the text. Each red circle gives the approximate location of the center of each area

currently at work in such a large area and in a such long period of time (archaeological research initiated in the beginnings of the twentieth century), we try here to give a brief account of the past and ongoing research carried out by Argentine scholars, mentioning the main sites, material evidence, and social processes under investigation. For those interested in deepening the knowledge of a particular subject, they can refer to the cited authors and their vast production. It must be highlighted that most of the papers on the archaeology of this area are available in Spanish, although currently more papers are being published in English.

Puna is defined as a highland in the Andean range, with an altitude above 3.200 m.a.s.l. and a desert environment, with a cold and arid climate. The topography is complex, including basins, valleys and ravines, which give origin to different microenvironments (see Fig. 2). In the Argentine Puna, most of the basins are endorheic, except for the San Juan Mayo River, which is part of the exorheic Pilcomayo river system. Vegetation is sparse and composed by xerophytic communities and the climate is harsh, with a wide thermic amplitude during day and high sun radiation. Traditionally, the Puna in Northwest Argentina has been divided into two sections: the northeastern sector, or the Jujuy Puna, with higher humidity and less cold (*Puna Seca*) and with a topographic continuity with the south of the Bolivian Altiplano, and the southwestern sector, encompassing the southwest of the province of Jujuy, west of Salta and northwest of Catamarca, which has a higher aridity and colder temperatures (*Puna Salada*). These sections are, as well, differentiated from the Peruvian and Bolivian highlands, which are characterized by a higher humidity (*Puna Húmeda*). The resources available in the region under analysis are also diverse and have permitted the development of agriculture, the grazing of camelids, and the use of other vegetable and animal resources, minerals of different types, and salt, among others (Ottonello and Krapovickas 1973; Haber 2000; Albeck 2000, 2001).

The archaeological history of South America has traditionally been divided in several periods (see "▶ South American Geography and Chronology"), which vary from author to author, depending on their theoretical viewpoint, the region of interest, and the local processes, among other criteria. Under the understanding that chronological periods are useful tools to

Archaeology of Northwestern Argentinean Puna, Fig. 2 Different microenvironments from the Puna of Jujuy. (Photographs taken by the authors)

order and expose the archaeological knowledge of the area, and not as rigid compartments or packages of traits, here we will follow the periodification used by most Argentine archaeologists, although the limits among periods vary from region to region.

The first inhabitants were hunter-gatherers and we can find them since at least 10,000 BP, although new research is pushing this date considerably earlier. They continued to hunt and gather to around 3000 BP. This period is usually called Archaic or it can be divided into Paleoindian and Archaic. Around 3000 BP the populations in our area of interest started growing their own crops and herding llamas and alpacas. This period is called Formative or Early Period (Raffino 1999; Aschero 2000; Olivera 2001). Although many archaeologists identify a Middle Period, characterized by the influence of what is known as Tiwanaku culture or style (from the Titicaca basin in Bolivia), there is no conclusive evidence in our area of interest of this influence or of a change in the pre-Hispanic populations that justifies separating such a period. Around 900–1000 AD starts the Late Period or Period of Regional Developments, which was a time of apparently more complex societies and of regional conflict, which made populations inhabit settlements in high places, called *pukaras*, or in large conglomerates. Sometimes this period is divided into two, Period of Regional Developments I (900–1200 AD) and II (1200–1450 AD). This period ended with the incorporation of the territory to the Inka empire, approximately around 1450 AD, which was later followed by the Spanish conquest, with the first Europeans entering our region in 1536 AD (Raffino 1999; Nielsen et al. 2015).

The First Inhabitants

Since at least 10,000 AP, our area of interest was inhabited by small groups of hunter-gatherers, which moved through the whole area to harness different available resources. They hunted camelids, rodents, and birds, gathered an array of plants, and lived in camps. They used weapons with lithic points and painted rock art. Probably the weather was not as the one present in the area today. Glaciations, volcanic eruptions, and variations in humidity and temperature were processes that modeled the environment in those times affecting the resources available for these populations. Studies carried out in the Argentina Puna and the Bolivian Altiplano have shown that the conditions toward the end of the Pleistocene were more humid and cold, becoming drier and warmer around 8500–7500 BP (Aschero 2000).

The earliest known sites include caves such as Huachichocana and Inca Cueva, in small valleys east of the Jujuy Puna, tributary to the Quebrada de Humahuaca. These sites have exceptional preservation, and their excavations have shown that these early populations lived in these caves, made fires in them and pits to store food and different objects, made clothes from leather and some textiles from vegetable fibers, and gathered a huge variety of plants. These populations also produced rock art, mostly consistent in different abstract geometrical motifs painted in the caves they inhabited or in other caves and shelters (Aschero 2000; Raffino 1999). Other sites in the Puna dated between 10,000 and 9000 years BP include La Cueva de Yavi and Hornillos 2 in Jujuy and Quebrada Seca 3 in the Catamarca Puna of Antofagasta (Aschero 2000; Yacobaccio et al. 2014).

These populations were highly mobile, with large exploitation areas and a seasonal pattern of mobility and circulation of information across long distances. Probably many of the sites from this period were part of nomadic circuits to which they returned periodically, to hunt, collect vegetables, and gather other resources. These populations made triangular projectile points without stem, in different rocks. They also had complex secondary funerary practices, like those documented in Huachichocana III, dated in 9600 BP, with parts of a young male skeleton wrapped and deposited near a fire pit and protected with stones (Aschero 2000; Yacobaccio et al. 2014). In the area of Antofagasta, it is frequent to register burial sites with evidence of reopening of graves or transportation of body parts, which has been interpreted as part of the high mobility of this populations and as a cult to ancestors and a continuity of their social participation among the living (López Campeny et al. 2015).

There is also evidence of the use of resources from other areas outside of the Puna, such as feathers, solid canes (*Chusquea* sp.), and earth snails (*Strophocheilus* sp.), all from the lowlands to the east, among others (Aschero 2000).

After 8000 years BP, with the increasing aridity of the environment, the groups of hunter-gatherers would have concentrated in certain places, with permanent availability of water and other resources. In this period, there is a strong increase in the use of camelids (mainly guanaco, *Lama guanicoe*, and vicuña, *Vicugna vicugna*), which would lead to the domestication of llamas (*Lama glama*) after 4500 BP or even earlier (see "▶ Alpaca and Llama: Domestication"). The concentration or reduction in mobility would also lead to the use of local raw materials for lithic technology (Aschero 2000; López 2013; Yacobaccio et al. 2014). These changes in the use of resources are linked to changes in the lithic technology as well in sites of the Puna of Jujuy and Salta, around 5000 BP, with fabrication of lithic artifacts made on blades (López 2013). The deep knowledge of the environment also included plants and their cycles, which led to different mechanisms to manage and use them (Babot 2016).

In the Puna of Catamarca, the sites of Quebrada Seca 3, Punta de la Peña 4, and Peñas Chicas 1 have been dated in this period. In the Puna of Salta, the sites of Alero Cuevas and Abrigo Pozo Cavado also present evidence of these processes. In Jujuy, Inca Cueva 4 continues to be inhabited, with burials that include elements from other areas. There is also evidence from this period in Inca Cueva 7 and in Alero Unquillar in the southern portion of the Jujuy Puna (Aschero 2000; López 2013).

Archaeology of Northwestern Argentinean Puna, Fig. 3 Projectile points from Archaic and Formative times from south of Pozuelos basin. References: (**a**) triangular with straight base and thin section; (**b**) large lanceolated (longer than 5 cm); (**c**) small lanceolated (shorter than 5 cm); (**d**) lanceolated with shoulder; (**e**) triangular stemmed with convex edge; (**f**) triangular stemmed with straight and straight serrated edge. (Extracted from Angiorama 2011)

In the southern Pozuelos basin, the evidence from this period consists in superficial evidence of projectile points distributed over all the different microenvironments (see Fig. 3) and rock art that is comparable to the art of this period dated in other sites. One of these sites is a cave with paintings and a shelter besides it, where a diffuse combustion structure was identified and dated around 10,000 BP (Angiorama 2011).

Early or Formative Period

This period is characterized by sedentary populations that produced their own food and lived in small villages. They grew vegetables that were domesticated in the Andean region, through a long process that continues in time, and probably with local practices of flexible management and production of local varieties. These vegetables included potatoes and many other tubers, quinoa, beans, and also species domesticated in other areas, such as maize, gourds, peanuts, etc. Agricultural practices involved the preparation of different extensions of land for cultivation, including sometimes the use of structures, and complex rituals related to these activities (Raffino 1999; Albeck 2000; Korstanje et al. 2015). Despite the fact that the Puna has been traditionally portrayed as a marginal and hostile space, with human populations "adapting" to it through a strong emphasis in animal production, recent research is showing the importance that plants had in the life of past societies, including gathering, agriculture, and other practices in between (Haber 2000; Babot 2016).

They also herded llamas, which had a very important role in the economy from this period and the subsequent ones, as they provided not only meat but also wool and means of transportation for goods (Raffino 1999; Albeck 2000; Olivera 2001). However, probably, they also continued hunting and gathering other resources seasonally, involving mobility of the groups and a diversification of the resources exploited in order to confront a difficult environment. The zooarchaeological record shows that wild camelids continued to be an important resource for these populations and that both domesticated and wild camelids were the most represented species in dumps while other species scarcely appear (Olivera 2001).

They also started to produce their own pottery, for cooking, eating, drinking, and for ceremonial uses, in different styles, characteristic of each particular area, but that had a large distribution, probably by commerce or interchange. There is also evidence of networks of traffic and interchange between these societies and other regions with other products, even of long distance interchange, from the Pacific coast to the forests east of the Andes range. They were probably the continuation of those from previous times (Raffino 1999; Albeck 2000; Olivera 2001).

This period is better known in the southwestern Puna, in the province of Catamarca, where there is evidence of agro-pastoralist systems since at least 2400 years before present in the area of Antofagasta de la Sierra. The early pottery in this region (400 BC–100 AD) apparently indicates strong links with the north of Chile. However, later there is a stronger connection

with the valleys of Catamarca, evidenced by gray and well-made pottery, with incised decoration, or red with polychrome paint (Olivera 2001). Besides vessels, it is also frequent to find ceramic pipes. There is also a wide variety of other materials, including lithic technology, valve and stone beads, basketry, and bone instruments, among others. The rock art related to this period includes animal figures and other geometric motifs (Albeck 2000; Olivera 2001).

The sites in this portion of the Puna include permanent settlements in the bottom of river basins, like Casa Chavez Montículos, which had round houses built with stone foundations and walls made probably of mud or *adobes*, now seen as mounds. There were other permanent settlements at the lateral gorges of the basin, like Punta de la Peña 9 or Corral Grande 1, where the domestic spaces were used for multiple activities and continued to be occupied even after the Spanish conquest. These sites were integrated to other temporary posts in higher gorges, used sometimes during the year for hunting and herding, like Real Grande. A similar settlement pattern can be inferred for other parts of the Puna, where resources availability vary seasonally (Albeck 2000; Olivera 2001; Olivera and Vigliani 2000–2002).

The burials in this region were made either separate from the big settlements, in structures were several individuals were buried, in groups of burials with round or elliptical structures, or near the habitation and production spaces, with frequent opening and transportation of the bodies or parts of them, in a similar way to the previous period (Olivera and Vigliani 2000–2002; López Campeny et al. 2015).

Another formative village in the Puna of Catamarca is Tebenquiche Chico, near the salt flat of Antofalla. It has circular dwellings made of stone associated to the agricultural areas, which also have structures for water supply. The pottery is diverse, with local types, others related to the valleys of Catamarca and others to the area of Atacama in the North of Chile. Nearby there are also sites that have been used repeatedly over a long period of time for complementary activities, like hunting or gathering of lithic resources, among others (Albeck 2000; Haber 2007).

Also in Catamarca, to the south of Antofagasta, the basin of Laguna Blanca was the settlement of a series of villages from this period, with circular stone structures around a patio, and also other residences isolated and dispersed in the landscape. The isolated ones and those grouped in villages share a common architecture and material culture, which allows the researchers to infer that there was no functional difference among them. All these habitation structures are located near the agricultural areas, like in most of the Puna, and their material culture shows evidence of diverse productive activities. The pottery types present are similar to those described in the Antofagasta Region, which are related to those in the valleys to the east. As well, there is a continuity in the modes of construction and habitation that is only modified with the arrival of the Inka Empire, which has led to propose that the Formative or Early Period continues way after the end that has been conventionally identified for it in the Argentine Archaeology. Even more, the productive activities and the configuration of the landscape probably would have had strong continuities until very recent times (Delfino et al. 2015).

In a similar way, in the same province of Catamarca, but to the south, in the area of Chaschuil, the research being developed allows to suggest that the Formative or Early Period and its social strategies or ways of life do not end like conventional chronology postulates in the area. It has been shown that the populations in this area lived with similar settlement patterns, economies, and materiality from the first to the thirteen centuries of the era. The transitional Puna has shown an important role in the circulation between different neighbor environments. Several small sites with one or a few associated subcircular structures have been identified, probably related to activities such as the use of lithic resources, hunting of camelids, and probably gathering of other resources (Ratto et al. 2015).

There is not much information about this period for the northeastern Puna. In Jujuy, near the frontier with Bolivia, in Cerro Colorado, and La Quiaca Vieja, occupations from this period have been identified. They consist in small villages of farmers that settled in small valleys where

they grew their crops and built their houses with dried mud bricks (*adobes*) and which results in sites with mounds after their disintegration. The pottery from these settlements is technologically similar to the one that was produced in the area in the following period, but there are shapes present that do not appear after 1000 AD, like ceramic pipes (Albeck 2000).

There are also occupations in caves and shelters, which might have been integrated with other sites. Some of these have the earliest dates for pottery in Northwest Argentina, together with those of the Antofagasta Region. These include Inca Cueva 1, Tomayoc, Cueva Cristobal, and Pintoscayoc. Moreover, in Huachichocana, there is early evidence of domesticated vegetables dated around the 600 B.C. and 300 AD, although it has been suggested that these probably came from the lowlands. The rock art identified for this period is present in Inca Cueva, which includes motifs of human figures in groups or lines, sometimes with radiating lines over their heads. This style has also been identified in other parts of the Puna of Jujuy (Albeck 2000; Olivera 2001; García et al. 2015).

In the locality of Alto Sapagua, there are agricultural fields associated to a settlement with the same name, which has habitation structures with ceramic fragments that have been assigned to this period, together to other materials such as projectile points, and beads made on different resources, among others. Several burials with abundant material have been excavated in the vicinity of the structures and have radiocarbonic dates of the end of our period of interest (around 1000 AD). There is also rock art with representations of camelids in the area (García et al. 2015).

In the southern portion of the Miraflores-Guayatayoc basin, the site Torre can also be included in this period. It consists of a group of disperse circular structures that would have been used for habitation (Albeck and Zaburlín 2008). In the same region, in the site of Santa Ana de Abralaite, it was possible to identify an occupation from the end of this period, related to ceramic types characteristic of the Quebrada de Humahuaca, but with petrographic evidence of being locally produced (Zaburlín 2014). In a similar way, in a rubbish mound in the site of Moreta, in the basin of Pozuelos, the lower levels have yielded ceramic fragments, some with decoration comparable to types from Humahuaca, but with petrographical composition comparable to the local pottery. These are associated to dates around 700 and 800 AD (Pérez Pieroni and Angiorama in press).

In the northwest area of Jujuy, in the frontier between Bolivia, Argentina, and Chile, archaeological surveys allowed the identification of several archaeological sites with evidence from these moments irregularly distributed. They are small groups of round habitation structures and some isolated round structures for daily activities. The pottery associated in some of the sites is ordinary, polished, and sometimes incised, related to the types defined in the oriental portion of Jujuy. Other sites to the west of the region have polished pottery, similar to the types defined in the Atacama region in Chile. The lithic tools are abundant and diverse and made on several types of rocks. It has been proposed that the occupations would have been temporary but persistent, probably related to other settlements in lower areas and oriented to activities such as seasonal grazing of animals, hunting, gathering eggs, fabrication of lithic artifacts, and the working of copper minerals (Nielsen 2004).

Between the Puna of Jujuy and Catamarca, in the Puna of the Salta Province, the archaeological work carried out in recent years in the Quebrada de Matancillas has shown that also here the human populations had an agricultural economy, with pottery similar to the early ceramic tradition identified for the lowlands of Jujuy. There is evidence of diversity of vegetable species cultivated and/or manipulated and of domestic and wild camelids. The occupation of the sites was not long, as the radiocarbon dates obtained only encompass 400 years. There is also evidence of networks of interaction, probably related to trade, such as nonlocal lithic raw materials and the signaling of mobility circuits with rock art (Muscio 2007).

Late Period or Regional Developments

This period has been characterized in South America as one of diversification of ethnic groups (or Regional Developments) and as a period of

conflict between these groups, which would have led to the development of settlements in high defensive places, with visibility and strategic localization, known as *pukaras*; or to the concentration of population in large conglomerate settlements. Nonetheless, in the area of the Puna, the archaeological record does not support a vision of endemic conflict, as most of the large conglomerates that emerge in this region are not located in defensive places but on the bottom of river valleys or other areas, more related to the availability of farmable lands. Many of these groups have been identified with those that the Spanish *conquistadores* found when they entered our region of interest.

It has been proposed, as well, a change in productive systems, such as a supra domestic organization of agricultural activities, with a more intensive use of the land and separation from the habitation spaces, although in some places the organization of the previous period continues through time (Korstanje et al. 2015).

The northeastern Puna in Jujuy shows a concentration in large settlements in this period, probably with a considerable increase in the size of the populations. These settlements are usually closely related to areas prepared for agriculture. Mostly, they have rectangular habitation structures, but there are also some with round ones. Moreover, there is evidence of smaller sites, consisting of a couple of structures in between agricultural fields, or in places apt for farming animals, which were probably temporal posts for herders (Ottonello and Krapovickas 1973; Albeck 2001).

For this portion of the Puna, archaeologists have traditionally identified two material culture styles or traditions, which have later been correlated to the ethnic groups found by the Spanish *conquistadores* (Krapovickas 1983). One of them was called Yavi or Yavi-Chicha, and it was distributed in the Yavi-La Quiaca basin and the north of the Pozuelos basin in Argentina, in the valleys of the south of Bolivia and part of its highlands, and in the basin of the river Grande de San Juan in Bolivia and Argentina, where it is called San Juan Mayo River. It was first recognized through fieldwork in the Yavi Chico site, but it includes important conglomerate sites both in Argentina and in Bolivia (Krapovickas and Aleksandrowicz 1986–1987).

These conglomerate sites consist of rectangular structures around a patio, constructed most frequently in stone. The pottery is the aspect of the material culture most commonly used to identify this tradition, especially through the properties of the ceramic pastes, which characteristically exhibit white inclusions of pellitic sedimentary rocks. This pottery also has characteristic shapes (some are shown in Fig. 4), is frequently slipped and polished, and is very well made and cooked. Sometimes, different motifs are painted in a thin black paint over the color of the surface or of the slip (Ottonello and Krapovickas 1973; Ávila 2009; Cremonte 2014).

The other tradition was called Casabindo or Agua Caliente, and its territory included the Miraflores-Guayatayoc basin and the south of Pozuelos basin. Large sites as Doncellas (or Aguas Calientes) and the Pukará of Rinconada were included in its area of distribution (Ottonello and Krapovickas 1973; Albeck 2001). The early archaeological research made in some of these sites involved the excavation of a large quantity of tombs made in small caves or shelters, which allowed the recovery of a huge number of artifacts, including an important quantity of wooden tools, gourds, textiles, etc. The findings also included pottery that shows characteristic shapes and sometimes a very simple painted decoration (some examples are shown in Fig. 5) (Krapovickas 1983).

The use of lithic instruments was also important in this period. It is common to find shovels made of slabs, which exhibit the same shapes all over the Jujuy Puna. In addition, small triangular projectile points with stem or without stem and a concave base were made on different rocks. Moreover, some of the sites that have pottery of the Casabindo style have stone menhirs, such as the Pukará of Rinconada, Doncellas, and Pueblo Viejo de Tucute (Ottonello and Krapovickas 1973; Albeck 2001).

Some of the main sites in this period include the Pukará of Rinconada, in the Pozuelos basin, which is a defensive conglomerate, located in a

plateau that has a unique access and has an excellent and strategic view of the basin. In the neighboring plateaus, the local populations buried their dead in small caves and painted a high diversity of motifs in rock art panels (Albeck 2001). This was the only defensive site known until recently, when

new surveys in the Pozuelos basin have located the already mentioned site of Moreta. But as it was referred, this Inka facility was settled over an earlier village and associated to areas prepared for agriculture and to corrals for livestock. In a low hill next to the settlement, there is a defensive site, previously unknown, with a strategic view of the bottom of the basin, which probably was contemporary with the main settlement (Pérez Pieroni and Angiorama in press).

To the south of Pozuelos, in the basin of Miraflores-Guayatayoc, there are a number of large conglomerates but located in the bottom of valleys and in association with agricultural fields. One of these is Doncellas or Agua Caliente de Rachaite, which is a conglomerate distributed on both sides of a temporary stream, with mostly rectangular habitation structures and agricultural fields in its vicinity. There is also a structure with steps in the settlement, which has been interpreted as a ritual structure. It also includes a large quantity of tombs in caves, which were excavated by the early archaeologists of the area (Albeck 2001). Pueblo Viejo de Tucute is another large conglomerate, which has a defensive site in its vicinity, with only one access, limited by defensive walls, although the relation among the two sites is not yet clear. The settlement is also particular because it has round structures instead of the more common rectangular pattern. Other settlements in this area include Pueblo Viejo de Potrero, Tabladitas, Ojo de Agua, and Calaverioj, among others (Albeck 2001).

A particular type of sites includes mounds that are probably the result of structures built with mud bricks and that are located to the north and east of the Pozuelos basin. Two large ones are Yoscaba and Pozuelos, which have pottery that corresponds to the Yavi or Yavi-Chicha style. The excavations did not allow to identify the original shape and size of the structures (Albeck 2001; Albeck and Zaburlín 2008).

The northern part of the Argentine Puna also has important sites, like Yavi Chico, which is a settlement in a terrace by a river with the same name. The lowest part of the terrace was used for agricultural fields and the highest one for habitation structures. The burials in these sites were not made on caves, like the previous ones, but inside the dwellings. Another site is Cerro Colorado 1, near the town of La Quiaca, which is located over a hill, with an excellent view of the surroundings. It is a semi-conglomerate with rectangular structures (Albeck 2001).

Besides these large conglomerates, there is evidence of smaller sites related to productive areas, as we mentioned before. In the area of the southern basin of Pozuelos, it is common to find isolated structures or small groups of them, mostly round, in between areas prepared for agriculture, frequently also with a corral in its vicinity, and sometimes also with rock art. The excavation of many of these sites showed that all correspond to this period, especially after 1200 AD. There is rock art painted in different rock formations and caves, which becomes widely distributed. Most representations are of camelids or anthropomorphs. The resources in higher areas were also used in activities such as hunting and recollection of minerals, rocks, and others, in small sites of temporary use (Angiorama 2011).

Some of the large settlement and other small ones have structures called *chullpas* associated, built next to rock walls or in small shelters. Although they are smaller and constructively different than their homonyms in the Bolivian highlands, it has been postulated for both types that their functions could be more diverse than to be sites for burial but that anyway they represented the ancestors, real or imaginary, of the societies in these areas (Nielsen 2002; Rivet 2015).

In the Argentine portion of the San Juan Mayo River, which is closely related to the Puna to the east, recent studies on settlements of this period show that, like in the Puna, there was a concentration of the population in the large settlements around 1200 AD. These sites include a variability of sizes, from a few associated structures to large conglomerates (like Finispatriae, Cabrería, San Isidro, and Bilcapara). They are located in gorges tributary to the river, where there is permanent availability of water, and consist in groups of square or rectangular constructions of stones and earth (mud bricks). Besides the habitation structures, there are agricultural fields, corrals for animals, inhumations inside or outside the houses,

and other remains of activities. There are also structures with evidence of temporary occupation located in different microenvironments, probably linked to other activities, like seasonal grazing of animals, circulation, etc., and chambers in shelters or *chullpas* (Nielsen et al. 2015).

There is evidence that the traffic routes from previous periods continued to be used in this one. This can be seen through the products traded, in the presence of routes and sites associated to them, including offerings of minerals, and in the rock art, which frequently shows lines of llamas with their load (Albeck 2001; Angiorama 2011).

In the southwestern Argentine Puna, in the area of Antofagasta, apparently in this period, the populations abandoned the settlements in the bottom of the basin, like Casa Chavez Montículos, and moved to the piedmont to sites like Bajo del Coypar, which was a complex system of agricultural production, with artificial canals for water and with a settlement associated to it. Other big conglomerates emerge in this period, like the site of La Alumbrera, where there was a process of concentration of the population. This site has a wall surrounding most of it, and the structures of habitation are mostly rectangular with wall stones, but there are also other shapes present (Olivera and Vigliani 2000–2002).

However, an important part of the population continued to live in small sites related to the productive spaces, especially to those dedicated to herding, like Punta de la Peña 2. These settlements had a pattern similar to the ones of previous times, pattern that would remain even after the Spanish conquest. Another site belonging to this period is Peña Colorada 3, a defensive site, located on a high point with high visibility and a surrounding wall. This site is close to routes of circulation and a concentration of rock art. The decorated pottery in these sites is closely related to the ceramic styles identified in the lower valleys but have been made locally (Olivera and Vigliani 2000–2002; Cohen 2014).

In the rock art, some of the themes from the previous periods continued to be painted, like llamas and masks, among others, in panels located near small sites that would have belonged to small groups of herders. Other motifs, like those interpreted to represent *uncus* (the shirts that were used as main garments for men) and shield-like motifs, are located closer to the sites where population was concentrated. Some of these motifs are painted over motifs of the first group, what has been interpreted as an iconographic imposition that took place in the final centuries of the Late Period (Cohen 2014).

Inka Empire

This portion of the South American Highlands became part of the Kollasuyu during the Inka Empire, which was the largest empire constituted in pre-Hispanic South America (see "► Inca State and Empire Formation") and which extended over a diversity of environments. There are many hypotheses on the motifs for the Inka expansion to these regions, including the interest for mineral resources and the necessity of lands and resources for the rulers' extensive families or *panacas*, prestige, among others. It has been proposed that the Inka conquest in Northwest Argentina might have been driven by the interest in the exploitation of mineral ores (Raffino 1999), especially in the Puna where metalliferous minerals such as silver, copper, and gold are present, as well as other nonmetallic minerals (e.g., salt and turquoise). Nonetheless, many of these mining activities might have been obscured by later exploitations in the same mines, in colonial and republican times. Currently, different research projects are focused on studying the evidences of past mining activities and their development during Inka times.

As many authors have shown, the influence of this empire was not homogenous throughout the territories that they incorporated. Some factors that influenced these variations include distance to the core, the resources locally available, and the response of local populations, among others. Some spaces were highly controlled, with a large investment in infrastructure (administrative, defensive, agricultural, etc.), while other areas were controlled indirectly, with less integration and investment in infrastructure, including all the intermediate possibilities between these two (Alconini 2007). Depending on the interests of the empire on each of these regions, the Inkas applied

a diversity of strategies to incorporate them, as diplomacy and negotiations with local elites, incorporating them to the bureaucracies, asymmetrical redistribution of different resources and goods, military occupation, destroying of previous sites and/or structures, forced transportation of labor forces, etc. On the other hand, the answers of local populations were different and included resistance, cooperation, and negotiation, among others.

Material evidence left by this diversity of practices is varied and unevenly distributed. It includes architecture (military installations, agricultural infrastructure, administrative centers, an extensive road network, storage facilities, temples, etc.) and different kinds of objects (either imported or locally made with Inka influence): pottery, metal objects, and textiles, among others. Some of the most diagnostic materials of Inka presence are the pottery vessels that include new shapes, such as plates with an ornitomorph appendix (*platos pato*) (Fig. 6b), big bottles with a pointed base and a restricted neck with flaring rim known as *aríbalos* (Fig. 6d), and vessels with a very restricted neck and a lateral handle, called *aisanas* (Fig. 6a), among others. Mostly, these shapes are related to the storage and serving of drinks and foods (Raffino 1999). In the Puna, these vessels were most commonly not imported but locally made in the styles from the previous periods (the examples shown in Fig. 6 are made in styles of northeastern Puna of Jujuy). Specially, the Yavi-Chicha style was used to make a large quantity of these types of vessels, with the same pastes and surface finishes, incorporating some new decorative motifs on occasions (Ávila 2009). This provincial pottery was imported to many distant regions and sometimes even made in far places with local raw materials, interpreted as the result of *mitmakunas*, which were labor forces that were transported to different areas of the empire for different reasons (Williams and Cremonte 1997).

Archaeological sites from this time include portions of the Inka road, *tampus* (posts in trails), rock art, defensive sites or *pukaras*, shrines in mountains, agricultural complexes, etc. (Raffino 1999), reorganizing the conquest territory and the previous regional traffic of goods according to imperial interests. However, in most of Puna region, the Inka presence and investment in agricultural and possible mining activities do not appear to have had a dramatic impact in other dimensions of Puna herders and farmers' daily

Archaeology of Northwestern Argentinean Puna, Fig. 6 Some examples of Provincial Inka vessels from the Puna of Jujuy. A: object 2061 (44-1413 ME), Queta Collection, Instituto Interdisciplinario Tilcara (FFyL, UBA); B: object 1662 (43-1129 ME), Doncellas Collection, Instituto Interdisciplinario Tilcara (FFyL, UBA); C: object 1851 (44-1862 ME), Queta Collection, Instituto Interdisciplinario Tilcara; D: object MLP-Ar-(v)8177/(r) 111, Marquez Miranda Collection, División Arqueología, Museo Nacional de La Plata (Facultad de Ciencias Naturales y Museo, UNLP)

life (see Angiorama 2011). Some of these sites were constructed over previous ones from the preceding period. Many *tampus* are mentioned in the written sources of the European conquest, like the letter that the Spanish *Oidor* Juan de Matienzo wrote to the king in 1566 describing a possible road to link colonial Charcas jurisdiction (present-day Bolivia) with the Buenos Aires port (Krapovickas 1983).

In the Puna of Jujuy, there are many of these *tampus*, usually in proximity to different portions of the Inka trail, some of which are mentioned in Matienzo's letter. These include Toroara, Ojo de Agua de Cangrejillos, Rincón de las Salinas, Queta Viejo, Pozuelos, Yoscaba, and Calahoyo; many associated to previous settlements and with evidence of Inka architecture and provincial Inka pottery (Raffino et al. 1986). In recent years, studies have been undertaken in the small *tampu* of Santa Catalina, near the frontier with Bolivia, and Moreta, which is associated with the settlement mentioned before, occupied in the Late Period (Nielsen et al. 2015; Pérez Pieroni and Angiorama in press).

The Inkas were also present in the area of Antofagasta de la Sierra, in the settlement of La Alumbrera, where there is a sector built apparently during this period and pottery of provincial Inka styles. It has also been postulated that this empire expanded the agricultural area and improved the structures in the fields of Bajo del Coypar, where there is also evidence of Inka architecture (Olivera and Vigliani 2000–2002).

The Impact of the Spanish Conquest

The Spanish conquest involved a series of profound changes in the pre-Hispanic populations. Besides the well-known impact in indigenous demography, due to the conquest violence and the introduction of new diseases and of extreme forced labor system, during colonial times, individuals or entire indigenous communities were moved in order to ensure colonial control, evangelization, or the development of European economic enterprises, especially mining activities. Communities dispersed in different settlements were moved, for example, to *pueblos de reducción*, villages founded by colonial authorities or Spanish *encomenderos* (Spaniards who had the right to collect tribute from the indigenous population), or to developing mining centers. Therefore, many of the conglomerate settlements described above were complete or partially abandoned.

Nonetheless, indigenous populations showed a diversity of strategies to adapt to the colonial system. The archaeology of this period has begun to be systematically studied very recently, as part of historical archaeology, uncovering some of these strategies and complementing and sometimes defying the information available from historical studies of written sources.

As previously referred, mining activity had a very important role in the distribution of the population and the organization of the territory during colonial times (Becerra 2014). In the Puna of Jujuy, in the southern Pozuelos basin, archaeological work has led to the identification of different sites that emerged in this period around the mining and/or processing of gold and silver. There is a wide variety of such sites, from small sheltering structures with evidence of low investment extraction places to large settlements, which became very important, like the present-day towns of Santa Catalina and Rinconada, or became abandoned, like Antiguyoc (Fig. 7) or Ajedrez (Angiorama et al. 2017). Other interesting sites, related to the processing of minerals rich in silver, include reverberatory furnaces, which are frequently found in other areas of the Southern Andes (Becerra 2014). Most of these sites do not have other material evidence of colonial times, except for the large abandoned settlements, where it is frequent to find local pottery, with some new types from this period, imported earthenware, metal objects, and animal bones, among others (Becerra 2014; Angiorama et al. 2017).

Besides the mentioned villages in the Puna of Jujuy, other large settlements include Incahuasi in the Puna of Catamarca, where the extraction of gold led to its rapid growth in the eighteenth

Archaeology of Northwestern Argentinean Puna, Fig. 7 View of the gold mining site of Antiguyoc, in Jujuy. The white building is the church, which continues to be used in present times. (Photograph taken by the authors)

century. The architecture is very similar to the one recorded in the Puna of Jujuy, and the technology for the extraction of gold was of low investment (Lema 2012).

Despite the importance of mining activities, the spaces related to agriculture and pastoralism were not abandoned, as it is shown by the continue occupation or reoccupation of pre-Hispanic structures. In the southern Pozuelos basin, some of such structures have been identified, showing a deep continuity in the architecture and material culture, in large sites like Moreta, or in structures related to agricultural fields, like Río Herrana and Chajarahuaico. Only radiocarbon dates, some ceramic types and the eventual finding of bones of European animals allow to identify their colonial occupations. There are other isolated findings of the continuity in the use of pre-Hispanic settlements or of rock art made in this period in the Puna of Jujuy (Angiorama et al. 2017).

Nearby, in the upper basin of the San Juan Mayo River, excavations in a habitation structure in the site of Casas Quemadas identified evidence of occupation from colonial times, posterior to the Inka occupation, which would have no longer been related to agricultural activities, like in the previous period, but to the traffic with cattle that became a very important economic activity in the colonial system (Vaquer 2016). Similar evidence has been documented in the excavation of a structure in the San Lorenzo site, on the upper course of the same river, where a colonial occupation is evidenced only by the presence of bones of European cattle, while the architecture and the rest of the material culture have a marked continuity with the Late Period occupations (Nielsen et al. 2015).

To the southern extreme of the Puna of Jujuy, in the area of Coranzulí (Susques), there is evidence of the construction and reutilization of *chullpas* or chambers in shelters during colonial times, some of which were possible to date through radiocarbon in this period. There are also engravings in the walls that are clearly from these times, including crosses (Rivet 2015).

For the Puna of Catamarca, there is evidence of occupations during colonial times in sites like Tebenquiche, where some of the Formative or Early habitation structures were reused in this period, with pottery made following indigenous traditions, but with European influence, and glass beads. In the Antofagasta region, in Punta de la Peña, it was possible to identify and date occupations from early colonial period, with evidence of European fauna and fruits. There are similar evidences of colonial occupations in Peñas Coloradas. All of these contexts evidence a deep temporal continuity in the use of habitation spaces

and the early use of European resources and materials by native populations (Quiroga 2014).

Final Comments and Future Perspectives

Populations in the Puna have followed a complex historic path, similar sometimes to those of other areas of the Andes, but also with local particularities. The region and time period encompassed in this essay is large; so much of the variability probably has been understated. Besides, the development of the research and the information available for each of the sectors of the area and for the periods encompassed are not homogeneous, as there are profound differences in the knowledge of different regions. Nonetheless, we have seen that there is evidence of a deep history, with groups of highly mobile hunter-gatherers exploiting different resources and showing a deep knowledge of their environment. This knowledge led to the domestication of camelids, to the incorporation of agriculture, and to more permanent settlements in the Early or Formative period, which are issues that are in the center of archaeological debate (see "▶ Alpaca and Llama: Domestication" and "▶ Andes: Origins and Development of Agriculture"). The settlements are articulated in complex networks where the populations developed different complementary activities.

Some of the cited authors have emphasized that the modes of habitation, the productive activities, and material culture show a strong continuity from Early or Formative periods to very recent times, challenging the traditional chronology and the understanding of periods as packages of traits or of certain social processes (Delfino et al. 2015; Ratto et al. 2015).

On the other hand, some of the areas analyzed went through deep changes in the Late or Regional Development Period, particularly after 1200 AD, where population concentrated in conglomerates, sometimes in defensive places. It has been emphasized that in the Puna, in contrast to other neighboring regions like the north of Chile or the Quebrada de Humahuaca, there are very few defensive settlements in high places or *pukaras* (Albeck 2001). This could be the result of differences in the local social processes, which are not yet fully understood.

The incorporation of this territory to the Inka Empire is a very interesting topic being studied with dissimilar depth in each region but is showing that this incorporation was not homogeneous and that the Inkas used a diversity of strategies, which produced a variable influence and diverse materials results in each area.

Throughout its history, this area was not isolated. Archaeology shows constant connections with neighboring areas such as the north of Chile, the Southern Bolivian *Altiplano*, and the valleys to the east, among others. These relationships are complex and involved not only resources but also people and knowledge. We refer to the cited and further references for more information in this respect.

The archaeology of colonial times is just beginning to be undertaken, but it is showing that while in some places the conquest and the incorporation to the colonial system had deep impact in the configuration of the territory and its population, particularly through mining activities, in many sites, it is possible to observe a deep continuity in the use of the land, the architecture, and material culture. This shows that the conquest did not have uniform consequences for all the inhabitants of the Puna (Angiorama et al. 2017), and the archaeology of this period of time will certainly deepen our knowledge of the diversity of practices involved, being a rich area for interdisciplinary studies, particularly with historians and ethnohistorians.

Many of the populations incorporated to the colonial system have continued their historic paths, not without changes, to the present day. They are undergoing complex processes of acknowledgment and/or reconstruction of their identities. The current challenge for the archaeological discipline in this part of Argentina is to articulate and engage on these processes and to collaborate to elaborate a historical discourse that is useful in terms of present social relationships (Haber 2007; Delfino et al. 2015).

To sum up, it must be highlighted that, despite the extended vision that regards the highlands as difficult and inhospitable environments, as places of circulation or of extraction of resources (see discussions in Ottonello and Krapovickas 1973 and Haber 2000), the Puna is a space of a complex history and of diverse and rich social processes. The archaeology of this area is generating much valuable information to understand the social dynamics in the Andes for pre-Hispanic and colonial times and will probably continue to do so as more research is undertaken.

Archaeology of Salt in China

Shuicheng Li[1] and Rowan K. Flad[2]
[1]Peking University, Beijing, China
[2]Department of Archaeology, Harvard University, Cambridge, MA, USA

Introduction

In the vast territory current within the borders of China, there are many sources of brine that are widely distributed. Among the sources, Xinjiang, Qinghai, Tibet, and Inner Mongolia contain large lakes that naturally produce salt, whereas the rich brine in the southwest and the Three Gorges region of the Yangzi River are deeply buried and referred to as "well salt" in historical discussions. In contrast, Yunnan and Jiangxi produce rock salt while coastal regions in the southeast and elsewhere produce sea salt. Salt archaeology has only been a research focus since the 1990s in China, but in that time, a strong foundation for future work has been laid by intensive work in both inland and coastal contexts of ancient salt production.

Definition

Salts are crucial to human and animal diets because they enable a variety of regulatory functions of the body and in human communities serve crucial cultural roles as well (Adshead and Adrian 1992). Salt production has been important throughout history (Kurlansky 2002), and archaeological research on salt has been an important source of information about the role of salt in many historical and prehistoric contexts. Salt archaeology in China concerns a variety of issues, from the technology associated with the manufacture of salt to the various economic and social practices in which salt manufacture, trade, and consumption played important roles that can be investigated through the lens of archaeological data.

Historical Background

There was early recognition in China that "nature produces brine while people produce salt". Tradition holds that about 4000 years ago salt producing tribe was situated on the eastern coast of China with a leader called "Susha 夙沙" who later evolved into a salt deity. On the earliest writing in China, known as "Oracle Bone Inscriptions", found in association with sites of the late Shang Dynasty (ca. 1250–1050 BC), we already find characters related to salt. The earliest salt-related characters are pictographic combinations of a number of other graphs including "official" (*chen* 臣), "person" (*ren* 人), "brine" (*lü shui* 卤水) and "vessel" (*rong qi* 容器) (Fig. 1). This combination suggests that already at this time salt was a resource that was placed under state

Archaeology of Salt in China, Fig. 1 Oracle bone inscription character related to salt combining "official" (chen臣), "person" (ren人), "brine" (lü shui卤水) and "vessel" (rong qi容器)

control. In a number of early textual sources, records related to the control of salt are common, including the Warring States period *Guanzi*管子 (475–221 BC), the Han era *Yantielun* 盐铁论, the Yuan Dynasty *Aobotu* 熬波图, and the Ming Dynasty *Tiangong kaiwu* 天工开物, among others.

There is a long tradition of research into the history of salt in China (e.g., Vogel 1990; Yoshida 1993), but archaeological research started relatively late. In the 1990s, the discovery in the Three Gorges of a site with thick homogeneous deposits was associated with the long history of salt production in the region and naturally they were connected to the origins of this salt production. From 1993 to 2003, a collaborative project involving archaeologists from Peking University, University of California, Los Angeles, and the Sichuan Provincial Institute of Archaeology investigated this site and the broader context of prehistoric salt production in the Sichuan Basin (Li and Falkenhausen 2006).

Over the last couple decades there has been considerable development of salt archaeology in China, and significant sites related to the production of salt have been found in many locations, while at the same time, broader research programs have also developed in multiple regions. The two most important salt manufacturing sites that have already been excavated are the site of Zhongba in the Three Gorges region of Chongqing along a tributary to the Yangzi River and the site of Shuangwangcheng on the southern shore of the Bohai Bay of the lower Yellow River region in Shandong (Fig. 2). These two sites represent the brine-based well salt production of inland areas and the coastal production of sea salt in southeast China, respectively.

The Three Gorges region was among the regions where the earliest salt manufacture developed in China. According to historical records, the "Ba" people of the region were responsible for developing salt technology. By the Western Zhou (1046–771 BC), the Ba were using salt as tribute to offer to the Western Zhou king.

Zhongba stands as the origin point for salt archaeology in China (Flad 2011; Li and Falkenhausen 2013). The site is located on the Ganjing River, a tributary to the Yanzi, 6 km from the river mouth. Zhongba rises 12.5 m above the river channel and is composed of a midden of pottery and other archaeological debris dating from the Neolithic period through the Ming-Qing period (Fig. 3) – an activity span of more than 4000 years essentially encompassing the entire historical period of Chinese history.

In the late Neolithic (ca. 2500–1750 BC), the ceramic vessels used for salt production at the site were large, pointed-bottom vats with decorated rims and corrugated marks on the exterior (Fig. 4a). These vats were approximately 40 cm high and had large mouths and pointed or small, flat bases. They comprise over 70% of the ceramics at the site. Contemporary with these vats were a large number of pits with rounded bases. The mouths of these pits were approximately 1–2 m, and they are around 1 m deep. Some pits were lined with an yellow clay that was created to prevent liquid from seeping out of the pit. Some of the pits contained a number of rocks at the bottom, and some contained fragmented pottery. The nature of these facilities were similar in many ways to the salt production location of Pwaga in Uvinza, Tanzania known from ethnographic and ethnoarchaeological work (Connah 1996) and were probably related to efforts to make brine more concentrated in advance of evaporation or for filtering out impurities during the salt manufacturing process. The heating facilities used in salt production during the Neolithic were long and rectangular: 9.2 m long, 1.4–1.7 m wide, and 40 cm or so deep, but

Archaeology of Salt in China, Fig. 2 Map of China showing locations of salt production discussed in the chapter

Archaeology of Salt in China, Fig. 3 The site of Zhongba, in Zhong County, Chongqing

determining whether or not these features were used in conjunction with the aforementioned vats requires further research.

During the Bronze Age at Zhongba (ca. 1750–1000 BC), there was a relatively sudden change in the nature of the pottery associated with salt production with the appearance of small pointed-bottom cups (Fig. 4b). The earlier version of these cups took the form of a spinning top and had mouths around 6–7 cm wide and were about 6 cm tall. Later cups were longer and more horn shaped, with 5–6 cm wide mouths but heights between 10 and 14 cm. These cups peak at about 90% of the ceramic assemblage in the levels in which they are found. The process in which they were used within the salt production process is still a matter of debate among scholars. Some have determined that many of the upper parts of the cups are red whereas the lower parts are darker and greyer, with a fairly clear dividing line between the parts. This trait has been used as a line of evidence to suggest that the cups may have been placed into a layer of hot ashes to bake once filled with brine in order to create salt cakes. Because the capacities of these vessels are all very uniform, the resulting products would also have been similar in size suggesting a degree of standardization that may have been related to trade. There are many sites in the region from around this time period where small numbers of pointed bottom cups have been found and we can see that the trade network involving salt was already quite expansive.

During the Late Bronze Age to Iron Age period at Zhongba (ca. 1000–200 BC), there was yet another change in the ceramic vessels involved in the salt production process. At this time, the ceramic assemblage came to be dominated by rounded-bottom jars that were 15–20 cm tall, with a mouth diameter of about 10 cm, and

Archaeology of Salt in China, Fig. 4 (**a**) Pointed-bottom vats with decorated rims and corrugated marks on the exterior employed in salt production at Zhongba during the late Neolithic. (**b**) Pointed-bottom cups using at the site for salt production during the Bronze Age. (**c**) Late Bronze Age to Iron Age rounded-bottom jars used in salt manufacture

cord-marking on the exterior surface (Fig. 4c). These ceramics made up as much as 95–98% of the total ceramic assemblage from the associated layers and were found in abundance in association with workshop floors or nearby pits, including some that were associated with a level full of hole. Over time, these vessels became increasingly standardized in their shape and size. Accordingly, we can see the change in the degree to which the entire process of salt production at the site was becoming increasingly standardized as well. The organization of production became more centralized and the scale of salt manufacture also increased significantly as firm trade mechanisms were put into place. To date, the features involved in the heating of the brine during most of this period have not been identified, and so the precise way in which these vessels were used in the salt production process remains unclear.

Archaeological excavations have uncovered many examples of wattle and daub house foundations from this period that have remnants of a calcium carbonate sediment on their surface, probably left behind during the salt manufacturing

process. Nearby some of these foundations, several pits have also been found. The earlier pits during this phase are all round, similar to those from the Neolithic levels at the site. Later pits are rectangular. The longest exceed 4 m long and are 20–40 cm deep. The edges of some pits have a layer of yellow clay and some have pottery sherds embedded in the walls. Many examples have a white calcified crust on the surface as well. Inside these pits, excavators found numerous rounded-bottom jars and fragments of wood ash, and some also included rocks, which probably served a similar function to those in the round pits.

The heating facilities used for salt production at Zhongba during the Han Dynasty (202 BC–AD 220) were long and rectangular – more than 10 m long and 1–4 m wide (Fig. 5). Some had walls that were strengthened with stones, around which the sediment was pounded hard using a *hangtu* technique. These features would have been used together with iron pans in which the brine would have been boiled to produce salt. Eastern Han (AD 25–220) era decorated terracotta bricks from the Chengdu Plain area of central Sichuan depict salt wells, bamboo tube systems used to transport brine, salt production areas, and associated furnaces, all of which together comprised the system of facilities involved in the salt production process during the Han Dynasty.

Archaeology of Salt in China, Fig. 5 Long, rectangular facilities for heating brine and making salt dating to the Han Dynasty at Zhongba

The salt production furnaces used in the Tang Dynasty (AD 618–907) were round and arranged in an orderly set of rows, which established the subsequent organized structure of salt technology in the region. At another site in Yun'an Township of Yunmeng County, also in Chongqing, large scale Song (AD 960–1279), Ming (AD 1368–1644) and Qing (AD 1644–1911) Dynasty salt production workshops have been identified. At this site, brine wells, brine transportation troughs, brine storage pits, furnaces, and a jetty for facilitating boat transport of the finished salt have all been discovered.

The southern shore of the Bohai Sea has been an important location for the production of salt from antiquity to the present. Starting in the 1950s, archaeologists working on sites distributed in this region recognized that so-called "helmet-shaped vessels" (*kuixingqi* 盔形器), found in large quantities in this region, might have had an association with early salt production, but no evidence supporting this interpretation was forthcoming. Starting in 2002, archaeological survey in the region between the mouth of the Yellow River and the south shore of the Bohai sea discovered more than ten large clusters of archaeological remains related to the production of salt (Li et al. 2003, 2009). Each cluster of related material included numerous salt manufacturing facilities, between dozens and more than 100 in each case. After subsequent archaeological excavation, we now know these sites to date as early as the late Shang Dynasty, with some examples from Western Zhou, the Eastern Zhou, the Song Dynasty, and the Yuan Dynasty periods (Wei 2016).

Among these remains, remains from the terminal Shang and beginning of the Western Zhou (ca. 1000 BC) are the most completely preserved. One workshop covers an area of 660 × 900 m^2

with a central zone that contains an over 10 m long salt furnace that has a work space built behind it and two separate fireboxes (a front and a rear), along with two or three channels for smoke in the front (Fig. 6). Surrounding the salt furnace on four sides are a number of other related features including a brine well, evaporation pits, channels for the brine (Fig. 7), circular filtration pits, and flat areas for salt evaporation and collection. *Kuixingqi* vessels comprise over 95% of the ceramics collected in association with these features. These vessels are very similar to the rounded-bottom jars with decorated rims associated with Late Bronze Age salt production at Zhongba in the Three Gorges region. They average 20–22 cm in height, 16–18 cm in diameter at the rim, and have fairly standardized volumes (Fig. 8).

During the Springs and Autumns and Warring States periods (771–221 BC), it is clear that the size of salt furnaces in the region diminished and became more triangular in shape. These are around 4 m long and 85–100 cm wide. Their structures consisted of a fire door, fire chamber, and flues for the smoke. Inside the fire chamber, large numbers of jars with round bottoms were found. These vessels were similar to the *kuixingqi* of the Shang and Western Zhou period, but they are much larger in volume, with an average height

Archaeology of Salt in China, Fig. 6 Shang / Zhou period salt furnace 014B at Shuangwangcheng in Shouguang, Shandong with intact firebox and channels for heat and smoke and associated brine-storage pits

Archaeology of Salt in China, Fig. 7 Clay-lined brine storage pit with intact kuixingqi 盔形器 ceramic vessels from workshop 014B at Shuangwangcheng

Archaeology of Salt in China, Fig. 8 Shang / Zhou period kuixingqi 盔形器 "helment-shaped vessels" used in salt production from the site of Shuangwangcheng

between 60 and 70 cm and mouth diameter between 29 and 38 cm, reflecting a tremendous increase in the output of salt production at this time relative to the earlier period.

There is considerable order to the arrangement of salt production workshops during the Song and Yuan periods (10–14 centuries AD). They contain brine wells, salt furnaces, brine channels, and so forth. Furnaces are found lined up next to each other and range from 3 to 10 m in length. These include a work space, fire chamber, flues, storage rooms, and refuse pits. The nature of the kilns demonstrate that the objects involved in the evaporation of brine were rectangular or oval iron pans. There are some examples of small rectangular or oval stove props on top of the furnace flues which probably served as places to preheat the brine during the evaporation process. This type of feature was a technology that increased the efficiency of fuel use and continued to be employed in recent traditional salt production workshops such as those found in Sichuan into the twentieth century (see Vogel 1990; Flad 2011).

Key Issues/Current Debates

Based on the two examples discussed here, which are the only two examples that have been extensively excavated and published of the many examples of salt production locales known from across China, we have developed a much fuller understanding of some of the characteristics of early salt production sites in China in both the inland regions and the coastal areas. This work has revealed aspects of the technology of salt manufacture, the associated organization of production, the scale of output during different phases of operation, the nature of administration and control, and the relationship of production and exchange. These data are very valuable for addressing these and related issues and have established a strong foundation for our understanding of salt archaeology in China generally. Based on this foundation, during the past few years, additional work has started in many other locations including Gansu, Tibet, Yunnan, Hainan, Zhejian, Hebei, Jilin, Qinghai, Jiangxi, and Sichuan. This work has started a continuous stream of new information filling gaps in our knowledge and will form the body of research that fills out salt archaeology in China.

International Perspectives

Salt archaeology in China relates to a much broader field of the archaeology of salt production

globally. Salt has been an interest of archaeologists for more than a century, and after a couple of influential meetings about the topic in the 1970s (de Brisay and Evans 1975), the field of comparative salt archaeology has continued to grow lately with multiple recent conferences dedicated to the topic (e.g., Castello Huerta 2008; Weller et al. 2008; Li and Falkenhausen 2010) and field projects primarily focused on the major themes in the archaeology of salt in many regions of the world (e.g., McKillop 2002; Kern et al. 2009; Brown 2013; Harding and Kavruk 2013).

Future Directions

In addition to the broader historical and anthropological themes addressed by the research in China and globally, some recent work has attempted to develop scientific methodologies for convincingly identifying salt residue in prehistoric contexts, especially where ceramics are used in the evaporation process (Flad et al. 2005; Raad et al. 2014; Stoner et al. 2014; Tencariu et al. 2015). These techniques still have not produced convincing, universally applicable procedures, and more work is necessary on this subject.

Furthermore, in recent years, there has been an effort to begin ethnographic research at sites in inland China where traditional salt production techniques continue to be practiced. Examples include salt production localities in Tibet at the Mangkang 芒康 (Fig. 9) salt terraces, at the Yangpu 洋浦 and Eman 峨蔓 salt fields in Danzhou 儋州 on Hainan Island (Fig. 10), at the Duolunduo 多伦多 salt fields in Nangqian 囊谦, Qinghai, where the difficult processes of collecting relevant data have commenced (Xizang Zizhiqu Wenwu Baohu Yanjiusuo et al. 2010; Cui and Li 2013; Jia et al. 2015). This valuable work confirms that the ingenuity and vitality of technologies that have developed for thousands of years. The work also is an example that explores significant aspects of traditional culture, land, and resource use. If these traditions can be sufficiently well recorded and preserved such that we retain this important historical knowledge, it will help us maintain an understanding of the

Archaeology of Salt in China, Fig. 9 The Mangkang 芒康 salt terraces in Tibet

Archaeology of Salt in China, Fig. 10 The Yangpu 洋浦 and Eman 峨蔓 salt fields in Danzhou 儋州 on Hainan Island

diversity of human practices and thus serves as an important focus of both archaeological and heritage work more broadly in relation to salt production in China.

Archaeology of Salt in Japan

Takamune Kawashima
Shimane University, Matsue, Japan

Introduction and Definition

Seawater has been the primary resource for producing salt in Japan because of the absence of rock salt, salt lake, and salty soil (Kondō 1975). The only exception is salt springs which usually contain much less salt than seawater. Few places are known to have produced salt by salt springs in the early modern to the modern period. Salt production in Japan has developed along the seacoast which had suitable climatic conditions for producing salt. The first evidence of salt production was salt-producing pottery which had appeared in the Late Jōmon (ca. 1,500BC) (Kondō 1962; Kawashima 2012b, 2015). Salt pottery was distributed along the Pacific coast in eastern Japan (Fig. 1). While the tradition of the Jōmon salt production existed till the Middle Yayoi period in the northern region, in the same period, salt pottery appeared in the Inland Sea area which has been the most crucial salt production area in Japan till the contemporary period (Fig. 2). Salinity of seawater in Inland Sea is approximately 30–34‰ through the year. The area around Inland Sea has high fine weather rate, which is crucial for salt production. The reason that salt production occurred in the Inland Sea area in the Yayoi period is still unknown. Kondō (1984, 1994) suggested three possible scenarios of salt production in this

Archaeology of Salt in Japan, Fig. 1 Distribution of salt pottery in the Jōmon

area: diffusion of the salt production technique from the northern region, the invention of salt production in the Inland Sea area, and diffusion of the salt production technique from the Korean Peninsula. As there is no direct evidence of the scenarios suggested by Kondō, most researchers

Archaeology of Salt in Japan, Fig. 2 Chronological and regional distribution of salt pottery after the Yayoi period

have assumed that salt production techniques with pottery were invented in the Jōmon and the Yayoi periods independently, and after the Yayoi, the technique was gradually diffused and adopted on the coasts of Japanese Archipelago.

Key Issues/Current Debates/Future Directions/Examples

For the ancient salt production, Japanese archaeologists have constructed the chronological order and regional variation of salt pottery (Kondō 1984, 1994). These were based on salt pottery found distributed from Kyūshū, a southern island to Tōhoku region, and the northernmost Honshū. In order to concentrate seawater, seagrass was thought to have been used for pottery salt production. Ancient literature such as *Man'yōshū* and *Hitachi no kuni hudoki* describes the word "*Moshio*," which literally means seagrass (*mo*) and salt (*shio*). There is a famous shrine near Sendai, which keeps the possible ancient way of brine concentration. In their annual ceremony, they harvest seagrass and pour seawater on it. Then they boil the collected brine. This method could be just a ceremonial practice and not an efficient way to obtain dense brine. According to archaeologists testing this method, however, seawater could actually be concentrated by

seagrass (Hiroyama 1993; Watanabe 1991). Another evidence that seagrass was used for concentrating seawater are burned micro shells on the seagrass found in ash layers at the salt production sites (Watanabe 1991). This technique, possibly dating back to the Jōmon period (Abe et al. 2013), could have lasted at least until the appearance of salt terrace system.

After the establishment of the *ritsuryō* political system in the eighth century, tax was paid in kind, mostly by rice and in some areas by salt. In Nara, the ancient capital of Japan, archaeologists excavated many wooden tablets with letters indicating the kind of tax, name and place of the taxpayer, and so on. Numerous wooden tablets containing the word "salt" were found in the Nara area, as the result of collecting tax (Kishimoto 1998; Nara National Research Institute for Cultural Properties 2013). In addition to wooden tablets, salt pottery shards possibly used for making salt cakes were found at Jikidoin, a dining hall, of Saidaiji Buddhist temple (Oobayashi et al. 2007). These pots from various areas were containers of salt, although other perishable materials could be used for salt package. In the temple, over 80 ceramic vessels as the storage facilities were installed in the ground in lines, suggesting a possibility of salted food. During the eighth and the ninth centuries, there were some areas recorded as salt production places and on wooden tablets but where salt pottery gradually declined (Kondō 1994; Nara National Research Institute for Cultural Properties 2013). Some researchers claim that iron pan partly replaced salt pottery as indicated in some documents from the eighth to the ninth century. However, the mentions of iron pans in texts were so few that it is hard to assume that all the salt was produced by iron pan. The issue of introduction and function of an iron pan needs further archaeological investigation in areas where salt pottery was absent in this period.

In spite of the difficulty to prove the connection, introduction of iron pan and salt terrace might be combined as suggested by the possible hearth for an iron pan at the Taki Shibagaki site located in Noto peninsula (Toyama daigaku jinbungakubu kōkogakukenkyūshitsu and Ishikawa kōkogaku kenkyūkai 1991). While the salt terrace was found in the eighth century at Taki Shibagaki, in other regions salt terrace was scarce until around the twelfth century. Salt terraces were widely constructed in the medieval period. Salt terrace was constructed above sea level, so seawater was sprayed on sand terrace paved by clay, then after the drying of wet sand, salty sand on the ground surface was gathered to leach it with seawater. This type of salt terrace is called "*Agehama.*" In the medieval period, furnaces were constructed by various materials, such as shell powder, stone, and wickerwork. Typical small-scale salt production survived on the Japan Sea coast until the modern period, as the scale of sandy beach is small. Another type of small-scale salt production existed on the small beaches in northern region, but there iron pan was used to boil seawater directly because of the cold weather.

On the other hand, in the Inland Sea area, another type of salt terrace called "*Irihama*" was developed in the seventeenth century. The size of the terrace became larger and complex (Hiroyama 1993). In this salt terrace system, seawater supplied through the channels goes up to the ground surface by capillary phenomenon, and the surface sand accumulates high salinity which is leached by seawater to dense brine. However, since this system needed a larger tidal range and flat sandy beach, the distribution of this kind of terrace was limited to some areas. Owing to the increasing amount of salt production in the early modern period and transportation by ship, salt became more easily available. As the salt consumption increased, high-quality salt hardened in a small ceramic pot appeared (Ogawa 2008). Such potshards were mostly found in residential areas for high-ranked people living in large cities. While in the history of salt in Japan it is no doubt that the Inland Sea area was the most important place for the early modern salt production in terms of the amount of produced salt, small-scale salt production mentioned above was also vital for regional history.

After the modernization, even the relatively large-scale salt producers in the Inland Sea area faced the difficulty of competing with low-cost imported salt. The government had to reform the salt production system by the Salt Monopoly Law

(1905–1997), in order to protect domestic salt industry and to earn by increasing tax. During the period of the Salt Monopoly Law, Japanese society experienced high economic growth, and people got used to buying processed foods, such as soy sauce, soy paste, pickles, etc., which were previously homemade in rural area. The traditional customs concerning salt in the modern period were also collected by ethnologists in Japan (Shibusawa 1939). They recognized a regional variation as well as some common practices and beliefs in a wide area. Ethnological studies also reveal a kind of salt production or a way to obtain salt. For example, some inland groups floated the timber down the river to the coast, then boiled seawater with the timber or sold it to buy salt (Miyamoto 2007). In addition to ethnological examples in Japan, the ethnoarchaeological approach using examples from overseas proved to be useful in archaeology, especially for understanding customs and beliefs relating to salt and the use of salt in the past (Kawashima 2012a).

Although in Japan a large number of archaeological sites were investigated, the lack of adequately obtained information on salt production prevented a full understanding of salt production. Owing to the industrialization along the coast, the most important beaches suitable for salt production became reclaimed land (Fig. 3). Also, many important salt production sites could have been destroyed before they were adequately excavated. On the other hand, as the knowledge of salt pottery became more widely shared among archaeologists, the number of recognized salt pottery shards increased suggesting not only the daily use of salt but a strong connection between salt production and other industries such as horse breeding as well as the military organization. For further understanding of salt production and

Archaeology of Salt in Japan, Fig. 3 Salt terrace and reclaimed land in Yamaguchi prefecture. (Map was made using GSI Tiles by Geospatial Information Authority of Japan, https://www.gsi.go.jp/kiban/, and site distribution map by Yamaguchi prefecture)

transportation of salt, the reexamination of excavated sites could be useful. New methods in chemical analysis (e.g., Horiuchi et al. 2011) and component analysis of salt pottery could enhance possibility of clarifying the trading system, tracing the movement of pottery from the coast to the inland areas. The latest approaches could provide us with valuable data to carefully reconstruct the (pre)history of salt production.

Archaeology of Shamanism

Alice Beck Kehoe
Marquette University, Milwaukee, WI, USA

Introduction

An *archaeology* of shamanism could be written in a few paragraphs: shamans work in northeastern Asia and the North American arctic, and claims to

evidence of shamans rest upon objects strongly associated with ethnographically observed shamans in those regions. Only a very few archaeological projects have met these criteria.

Definition

At the outset, we confront the question, is there such a "thing" as "shamanism?" There historically were and continue to be Siberian persons designated as shamans, a Tungusic (Evenki) word. But shaman*ism*? It is an academic term popularized during the 1960s through Mircea Eliade's 1964 book and then by the former academic anthropologist Michael Harner. "Shamans" are conventionally described as persons able to make contact with, or enter, the dimension in which spirits reside, popularly assumed to require an altered state of consciousness, that is, "trance." This popular notion stems from Western stereotyping of "primitive religion," attributed to non-Western peoples under Western colonial regimes.

Key Issues

Contrasted with the paucity of empirically well-supported inferences of discoveries of shamans through archaeology, claims for recognizing shamans in archaeological data are multitudinous. The editor of the book *Archaeology of Shamanism* cites Mircea Eliade's 1964 *Shamanism: Archaic Techniques of Ecstasy* as that "into the orbit of which most subsequent works have been drawn" (Price in Price 2001: 5). With this unsound, pseudo-scholarly book rife with errors and fraudulent citations (Balzer 1990: 47–48) serving to frame most works seeking archaeology of shamanism, careful critiques are warranted.

This entry will describe archaeology that seems justified in interpreting data to represent shamans and then explain the weaknesses in work framed by Eliade's seminal book. Fundamental issues are involved, of empirically grounded inferences to the best explanation (IBE) versus conclusions deductively derived from unexamined assumptions. To put it simply, the issue is ground-truthing with directly associated data, contrasted with proceeding from an asserted but untested general premise, that "shamanism" is ancient, universal among hunter-gatherer societies, and tied to altered states of consciousness. Each of these postulates must be examined.

What Is "Shamanism?"

Michael Harner moved from New York to an affluent San Francisco Bay community to build his Foundation for Shamanic Studies. Harner proselytized "core shamanism," "the universal, near-universal, or common principles and practices of shamanism not bound to any specific cultural groups or perspective" (quoted in Alberts 2015: 148). Anyone, he taught, can practice shamanism by entering an altered state of consciousness experienced as a passage into an alternate reality. Harner insisted, at the 1998 meeting of the American Anthropological Association, that the experience is empirically true, that he and his followers observed an alternate reality and therefore *scientifically* validated it (Kehoe 2000: 82–83). Although Harner was sincere, what is seen by a person in trance while their body lies inert is not accepted as scientific observation of the natural world.

Eliade's "shamanism" is mystical. He asserted that "All history is in some measure a fall of the sacred. . .but the sacred does not cease to manifest itself, and with each new manifestation it resumes its original tendency to reveal itself wholly" (Eliade 1964: xix). Thus in the premise that "shamanism" is primordial (Fig. 1) and eternal, "the sacred" manifests *itself* through human consciousness. From an Eliade standpoint, an archaeology of shamanism would seek evidence of "the sacred," a singular entity forever repetitiously manifesting. This would not be evidence of human actions in science's natural world. Significantly, Eliade did not do fieldwork with non-Western communities, refusing invitations to visit Australian Aborigines or even American First Nations near his home in Chicago.

"Shaman*ism*" contrasts with "shamans" as actual persons in socially constructed roles. Like

Archaeology of Shamanism, Fig. 1 Painting within Lascaux Cave, France, Upper Paleolithic, c. 14,500 B.C.E. Popularly called "The Sorcerer," the human figure is imagined to be a shaman in trance. A scientific interpretation using Ockham's Razor suggests the man has been killed by the bison bull he attempted to hunt: that is, the most *parsimonious* explanation is based on known fatal attacks of bison bulls upon men. Nothing in the picture links it to historic shamans. The bird on a pole or tree may represent a named place or the man's name (Ockham's Razor: William of Ockham, English scholar, fourteenth century, stated that interpretations should use the fewest assumptions needed – the "law of parsimony"). (Credit line: Lascaux #12, La scène du Puits, Cliché N. Aujoulat, Centre National de Préhistoire, MCC)

all *-isms*, "shamanism" is an abstraction. Unlike pottery or lithics, it does not exist tangibly in material form. It is an academic construct based on a literally imperial categorization – by Catherine, Empress of Russia – borrowed by a poet, her friend Johann Wolfgang Goethe, later popularized within 1960s counterculture proclivities toward spiritual fulfillment and altered states of consciousness and, most recently, linked to political movements for indigenous peoples' rights: for a detailed, thoroughly footnoted, extensive overview, see Alberts 2015. Within this mushrooming growth is the particular interpretation of rock art proffered by David Lewis-Williams in a 1988 *Current Anthropology* article. In line with Eliade's focus on altered states of consciousness, Lewis-Williams interpreted paintings of elands to be representations, not of the hunted animals but of shamans' feeling themselves transformed into elands. Rock art also includes simple geometric forms; these, Lewis-Williams suggests, are "entoptic," seen within closed eyes. Arising from human neurophysiology, seeing them would be universal. Western science insists that all rock art has been produced by humans, contrary to some non-Western societies' belief that some is made by nonhuman beings. A thesis that explained rock art in universalistic terms appealed to many researchers.

Archaeological Evidence for Shamans in Territories Historically Host to Shamans

It is reasonable to interpret items as evidence of shamans in the archaeological records of Siberia, where Evenki and other small nations do provide the social role "shaman" (*šaman*). Rock art figures of humans with a hand drum, particularly if the figure seems to be wearing regalia with fringes or appendages, are plausibly recognized there as shamans (Devlet in Price 2001: 43–55; Martynov 1991) (Fig. 2). On the other hand, in *The Archaeology of Shamanism*, ethnographer Peter Jordan shows only perishable items (cloth, animal skins) and bones as material components of, in this case, Khanty *elta-ku* (the equivalent of *šaman*) (Jordan in Price 2001: 86–104). Absent the metal or carved bone or ivory appendages of shamans' regalia, there would be no strong archaeological

Archaeology of Shamanism, Fig. 2 Regalia of a Tungus (Evenki) shaman, collected 1788 for a German museum: reindeer skin coat sewn with sinew, red and black painted geometric patterns outlined in fine white sinew, attached colored cotton and silk bands and long fringes, and 70 metal appendages of iron, copper, and bronze representing tree of life, birds, sun, moon, humans, and metal bells. A leather, fringed cap, fringed leather apron to which were attached metal images of wading birds and eagles, leather boots representing light (left boot with copper discs) and darkness (right boot, red paint), and a copper plate mask complete the dress. A long painted leather scarf resembling a snake, a handsome leather belt, a leather pouch with dried plants, and a leather strap fastened to the back of the coat's shoulders complete the ensemble, with additional painted leather snakes, doll-like spirit helpers, tobacco pipe and pouch, and mirrors and pieces of copper and iron. As the shamans danced, the long fringes flared out around them, the bells tinkled, and the metal pieces jangled (Hauser-Schäublin and Krüger 2007). (Note: this photo shows the dress before restoration by the Göttingen Museum). (The credit line is Fig. 2 (before restoration). © Ethnologische Sammlung der Universität Göttingen (As 957). Photographer: Harry Haase)

evidence for shamans – and not all Siberian shamans wore such regalia.

Perhaps the best archaeological example of a probable shaman is a middle-aged woman buried nearly 2000 years ago in Chukotka on the western side of Bering Strait. Excavated by Sergei A. Arutiunov and D. A. Sergeev in the early 1960s, Ekven Burial 154, well preserved in permafrost, was filled with tools and ornaments including a mask and carved ivory objects

resembling metal appendages hung on Siberian shamans' coats (Smithsonian Institution ekven1.#tomb). Its location and affiliation to archaeologists' Old Bering Sea culture support Patricia Sutherland's argument that Paleo-Eskimo art developed from Siberian and East Asian Maritime hunting antecedents (Sutherland in Price 2001: 135–145).

Reviewing the data advanced by archaeologists and art historians for archaeological evidence of shamans in Inner Asia and Siberia, Francfort (Francfort in Francfort and Hamayon 2001:260) first distinguishes between Indo-Iranian cultural elements seen in artifacts and rock art and those better associated with forebears of historic societies with shamans. Then he assesses these, concluding that not until the second half of the first millennium CE does rock art show elements characteristic of shamans in the Turkic-speaking regions of northern Asia (Francfort and Hamayon 2001: 260; Martynov 1991: 180, Fig. 52, a *historic* Yakut painting of a shaman bedecked with fringes).

"Archaeology of Shamanism" Outside Historical Northern Shamans Territories

Lewis-Williams and Dowson state, in their abstract to their 1988 paper, that they were

> constructing a neuropsychological model of the apprehension of entoptic phenomena in three stages of altered states of consciousness. The utility of the model is assessed by applying it to two known shamanistic rock arts, San and Shoshonean Coso. It is then applied to Upper Palaeolithic mobile and parietal art to show that this art was also associated with altered states of consciousness. (Lewis-Williams and Dowson 1988: 201)

Problems with their model are:

- Their "entoptic" forms are simple, including parallel lines, circles, zigzags, waves, and dendritic branching. There is no a priori reason to interpret them as entoptic.
- The "three stages of altered states of consciousness" is a model not supported by most researchers (Helvenston and Bahn 2003).
- Neither the San of South Africa nor the Coso area Shoshone (western Great Basin, USA; Fig. 3) has or had shamans: they have ritual practitioners and healers. When these trained practitioners intently focus on their task, they are in control of their actions. Lewis-Williams' student David Whitley himself flatly acknowledges "ethnographic informants consistently and unanimously referred to rock art as made by shamans' spirit helpers" (Whitley 1988); the practitioners he calls "shamans" are *pohakanti*, "one who possesses or uses power" (Thomas et al. 1986: 271). Quinlan (in Francfort 2001: 189–205) critiques Whitley's claims, finding them poorly supported.
- To impute "altered states of consciousness" to Upper Paleolithic artists fails to take into account the esthetics and choices of their art (Francfort 2001: 252; Hodgson 2014), not to mention lack of evidence of altered states.

Twenty years on, Christine VanPool proposed increasing the "rigor" of archaeological analyses by using "a robust body of scholarly research" on "shamanism" (VanPool 2009: 177). She takes as premises (1) that "shamanism" equates with "religious practitioners. . .[who] initiate trance states, generally called altered states of consciousness (ASC), for the purpose of communing with spirits," and (2) "shamanism has been documented around the world" (ibid.). In other words, VanPool remains within Eliade's orbit. She asserts that "rock art researchers find that unmasked anthropomorphic figures are commonly associated with shamanism" (VanPool 2009: 182), which allows almost any figurative art to be interpreted as "shamanic" and concludes with invoking colonialist cultural evolutionism: "an older shamanic substrate might be reorganized or included into a newer religious system" of priests (VanPool 2009: 188). Paraphernalia may not differentiate between shaman and priest; the difference lies in "how they access the supernatural" (VanPool 2009: 183). If associated material does not mark shamans from priests and accessing the supernatural is ephemeral, what in the archaeological record could be determinative?

VanPool's bibliography does not include Price's edited volume *The Archaeology of Shamanism* nor the critical papers in Francfort and Hamayon's volume (both published 8 years earlier), although she does cite my critique, Kehoe 2000, to reject it. As with Lewis-Williams and Dowson, VanPool does not delve into the wide and varied pool of neurophysiologists and brain research, considering the popularized publications of Ronald K. Siegel to be sufficient authority, in spite of, as she footnotes, "Siegel and West (1975) found that it was critical to train their subjects in their clinical test when taking hallucinogenic drugs" (VanPool 2009: 180). Standing within Eliade's orbit, she takes this manipulation of clinical subjects to be similar to non-Western religious practitioners training apprentices. From the same standpoint, she uses data from Casas Grandes (Paquimé) and Pottery Mound, two late precontact Puebloan towns, to illustrate her method of recognizing shamans in nonliterate societies. Casas Grandes is on the intersection of major trade routes linking the American Southwest with Mexico and the Pacific coast with inland towns. That late in history, in towns Puebloan in many respects, a reader would presume anthropomorphic figures painted on pots and walls to represent priests and ceremonial dancers, but VanPool sees "entopic (sic) imagery" and transforming shamans.

Summary

The idea of "shamans," as primitive religious leaders universally in ancient societies and non-Western indigenous small nations, is accepted uncritically by many archaeologists. The foundational text by Mircea Eliade has been denounced by scholars conversant with his alleged sources, and a careful reading reveals his mystical concept of an undying "sacred" contacted by "shamans." An "archaeology of shamanism" was stimulated by a 1988 paper by South African anthropologist David Lewis-Williams, proposing that anthropomorphic and animal forms, and simple lines, in rock art represented shamans' visions while in trance. Premising cultural evolution from primitive shaman-led communities to later states employing priests is part of Western colonial legitimation, obvious in the attribution of "shamans" to colonized peoples in contrast to imperial powers' priests. The term "shaman" should be restricted to the Arctic-Subarctic societies with religious practitioners such as the Evenki *šaman*, archaeologically inferred from rock art anthromorphs showing shamans' attributes and from the very few burials with material objects associated with shamans in these regions. Because religions are dynamic constructs arising from historical situations, none can have persisted from Paleolithic times, nor can there have been a universal substrate religion or practice superseded in "civilized" nations by priests.

Archaeology of Syria-Palestine

Louise Steel
Faculty of Humanities, University of Wales Trinity Saint David, Lampeter, Ceredigion, UK

Introduction

The archaeology of Syria-Palestine (Fig. 1) reveals a complex mosaic of interconnecting cultures with close relations to the ancient civilizations of Egypt and Mesopotamia, as well as with the surrounding cultures of the East Mediterranean, during the Bronze and Iron Ages (mid-fourth/third-mid first millennium BCE). As such Syria-Palestine was the ultimate contact situation, a place where individuals from very different social and material worlds interacted closely, sharing ideas and knowledge. The region was home to some of the earliest known fortified towns and cities; in the north these were literate from the mid-3 millennium BC, and texts from sites such as Ebla and Mari provide us with a unique insight into international politics, local religious practices, and social organization. Given the strategic position of Syria-Palestine, it was inevitably witness to countless military campaigns and successive empires between the late fourth and first millennium BC, indeed continuing down to the present day. Detailed and increasingly sophisticated archaeological exploration and

Archaeology of Syria-Palestine, Fig. 1 Map of Syria-Palestine showing sites mentioned in text

interpretation continues to shed light on Bronze and Iron Age settlement allowing a more nuanced understanding of the lives of the ancient communities in the region.

Definition

Syria-Palestine (also commonly referred to as the Levant) comprises the region of southwest Asia bounded by the Mediterranean Sea to the west, the Amuq plain to the north, the Sinai desert to the south, and the upper reaches of the Euphrates river to the east. It can be subdivided into a number of smaller regional entities according to geography and external influences. The two main areas of the northern Levant comprise coastal Syria, lying between the Mediterranean Basin and the Orontes River, and the uplands of inland Syria, between the Orontes and the Euphrates. The Barada river rising in the Anti-Lebanon Mountains watered the Damascus Oasis (al-Ghūṭah) – a large and fertile tract of land supporting settlement from at least the second millennium BC. To the south of the oasis is the basaltic region of Hawran, separating Syria from Transjordan. In antiquity the northern

Levant (Syria) fell within the cultural and political orbit of Mesopotamia. The central area of the Levant (modern-day Lebanon) is a narrow coastal strip, the homeland of the Phoenicians; this is bounded to the east by the Lebanon mountains, the Beqaa valley, and further east by the Anti-Lebanon mountains. The southern Levant is similarly divided into two zones by the River Jordan and Dead Sea. The western zone, Cisjordan, comprises a wide coastal plain and the highlands of mount Carmel, the Judean Hills, and the hilly region of Galilee. The Jezreel Valley in the northern part of this region provides an important route east-west. This area was the homeland to the ancient Canaanites, Philistines, and Israelites and was heavily influenced culturally and politically by ancient Egypt. To the east of the River Jordan lies an area of uplands and plateaus, known as Transjordan.

The chronology of pre-Achaemenid Syria-Palestine (Sharon 2014) is defined by ceramic seriation – significant changes in pottery styles over time. Absolute dates traditionally derive from cross-dating, using named Egyptian or Mesopotamian artefacts found in sealed contexts, but increasingly radiometric dating is being used to construct a more secure chronological framework (Toffolo et al. 2014). The late fourth-third millennium BCE covers the Early Bronze Age, the Middle and Late Bronze Ages equate to the second millennium BCE, Iron Age I covers 1200–1000 BCE, and Iron II (down to the Babylonian/Achaemenid Empire) largely correlates with the first 500 years of the first millennium BCE. These chronological phases largely correspond to significant developments in the social organization of the region: urbanization and the development of states through to the emergence of large regional empires.

Historical Background

The earliest archaeological activity in the southern Levant, in the nineteenth century, was largely inspired by an interest in the Bible (Davies 2004). The pioneer of biblical archaeology was the American clergyman Edward Robinson, who developed an historical/biblical geography of Palestine by matching modern Arabic names to biblical Hebrew names, albeit not always accurately. In 1865 the Palestine Exploration Fund was established with the express aim of surveying Palestine to provide a geographical background to the Bible. Some of their earliest work included the survey of the ancient water system of Jerusalem by Charles Warren, and in 1914 T.E. Lawrence and Sir Leonard Woolley (2003) completed a more detailed archaeological survey of the southern Levant, the so-called wilderness of Zin. Woolley and Lawrence also excavated the (Neo-)Hittite site of Carchemish on the Euphrates for the British Museum between 1912 and 1914.

The archaeological landscape of Syria-Palestine is characterized by tell sites – mounds formed by the detritus of continuous occupation over many centuries. These dominate archaeological narratives, being the focus of excavations over the past 150 years or so, while the rural hinterland is less well researched. While these tells proved challenging for the nineteenth and early twentieth century archaeologists, they also aided the development of archaeological techniques as demonstrated by Sir Flinders Petrie's excavations at Tell el-Hesi in 1890. Here, Petrie not only introduced the principles of stratigraphic excavations to Palestine but was also able to demonstrate the validity of his ceramic sequence dating by correlating his typological sequence against the stratigraphy of the tell. Important sites such as Megiddo, Gezer, and Ugarit (Minet el Beida and Ras Shamra) were excavated in the early years of the twentieth century, but archaeologists Gottlieb Schumacher, Robert Macalister, and Claude Schaeffer struggled with the complexities of the multiple layers of occupation and the sheer quantities of artefacts uncovered. At Byblos French archaeologists Pierre Montet and Maurice Dunand excavated the site in arbitrary 20 cm levels, creating an artificial stratigraphy, obscuring details of site formation. Instead, it was Reisner's excavations at Samaria where we see the first real understanding of tell formation and the necessity for meticulous recording, including architectural plans and photography. This was taken forward by William Albright at Tell Beit

Mirsim, albeit with a primary focus on pottery context rather than stratigraphy to interpret the results. Kenyon's excavations at Jericho further established the importance of stratigraphy and the use of the Wheeler-style grid system as standard. These approaches to tell archaeology have formed the basis of ongoing excavation in Syria-Palestine throughout the twentieth century up to the present, although regional surveys are increasingly helping to supplement our understanding of human interactions with the landscape (e.g., Wilkinson 2003), alongside some excavation of small, rural sites (e.g., Fall et al. 1998).

Over the past 70 years, modern political events have severely impacted upon archaeological research throughout much of Syria-Palestine. While dam construction in the late twentieth century has obliterated many sites in the area of the Syrian Euphrates, it likewise served as the impetus for systematic archaeological exploration of the region (Cooper 2006, 5–6). More destructive still have been the civil wars in Lebanon and Syria and the intifada in the Palestinian territories. Nonetheless, modern technologies have increasingly been employed to help record, preserve, and protect archaeological remains; for example, satellite imagery has been used to document the damage and destruction of archaeological sites in the Syrian civil war (Casana and Laugier 2017).

Key Issues/Current Debates

Initial interpretations of the archaeology of the southern Levant were informed by biblical sources. For example, the destructions at the end of EB III and appearance of new pottery and metal styles in MB I were equated with the Amorite incursions recounted in the Bible (Kenyon 1979, 145–6); similarly the Iron II sites at Samaria, Megiddo, and Beersheva were equated with the kingdoms of Israel and Judah (Kenyon 1979, 258–85). More detailed knowledge and understanding of the intricacies of the material record and the application of cultural-historical approaches have resulted in the archaeological narratives being placed within trajectories of social complexity, namely, the emergence, floruit, and decline of civilization. Also significant are more nuanced understandings of the relationship between material culture and cultural identity. The key metanarratives currently used to interpret Syria-Palestinian archaeology are urbanization, secondary state formation, empire, interconnections, and migrations/population movements. There has also been considerable debate over significant material changes in the archaeological record and the decline and collapse of urban centers and state systems, both at the end of the EBA (Kennedy 2016) and at the Bronze-Iron Age transition (Ward et al. 1992).

The EBA in the southern Levant is typically characterized as a period of increasing social complexity, culminating in the appearance of towns in EB II–III (Joffe 1993; Miroschedji 1989). Around 50 fortified EBA centers have been identified in Cisjordan, including Jericho, Ai, and Arad. These range in size between 3 and 25 hectares. The fortified walls had stone bases and mudbrick superstructures built on earthen ramparts and were protected by semicircular or rectilinear towers. The gateways were protected by flanking square towers. Inside the walls there were blocks of houses with courtyards and a network of paved streets. Public buildings are attested in EB III, most notably at Megiddo (Building 3177) and Tel Yarmuth (B1 and B2). These were substantial multi-roomed structures with inner courtyards. Recently, Chesson (2015) has questioned whether these settlements should in fact be identified as urban centers, noting a lack of distinction between the material habitus of rural and non-rural settlements and no evidence for the development of surplus redistribution economies. Instead she interprets these sites as egalitarian walled communities.

Urbanization is a later phenomenon in the northern Levant (Cooper 2006), dating to EB III–IV (the latter half of the second millennium BCE). Unlike the southern Levant, here there is clear evidence for settlement hierarchy, with large central places surrounded by smaller satellite settlements in the hinterland. The urban centers, or citadel cities, are characterized by a walled upper town, the location of the palace and temples, and a lower town fortified by walls built on a rampart.

A number of these cities have been excavated, most notably Ebla (Matthiae 1981). There is also clear evidence that these towns functioned within an early state system, as is evidenced by Palace G at Ebla and its important archives (some 17,000 documents written in the cuneiform script), which document a redistribution economy, treaties, and trade with other towns, and also literary texts. There is some evidence for gift exchange between Ebla and Old Kingdom Egypt in the form of a Pepi I inscribed stone vase fragment. Mari on the Euphrates (Margueron 2014), which lies at the interface between Mesopotamia and the Levant, was an important mediator of cultural and economic influence in Syria and in particular was in close contact (not always peaceful) with Ebla. Culturally, Mari was situated within the Mesopotamian sphere of influence, as is indicated by the lapis lazuli bead inscribed with the name of Mes-ana-pada, ruler of Ur, found in palace P1, and the fine stone sculptures dedicated in the Temple of Ishtar. There is also evidence for attached craft specialists in the palaces, who produced luxurious goods from traded commodities (lapis lazuli, gold, and silver). These might be placed in elite burials, such as the royal tombs located on top of the acropolis of Umm el-Marra. Here finds included silver drinking equipment and jewelry made from gold and semi-precious stones (Schwartz et al. 2006).

There is an apparent break between the urbanized communities of the EBA and MBA-LBA. Many EBA towns were abandoned – this has been variously attributed to climate change (Kennedy 2016) or military activity, such as the sack of Ebla by the Akkadian rulers – but by the second millennium BC, urban centers flourished along the coast of the Levant and in the region of the Syrian Euphrates, characterized by a new material habitus (architecture, metal objects, and pottery). These changes are commonly associated with the Amorites (Amurru of Akkadian texts and Martu in Sumerian) – a population group identified from Mesopotamia to Syria-Palestine (Burke 2018). In the north we see the development of cities controlling substantial territories, such as Ugarit (Yon 2006) and Alalakh (Woolley 1955); these typically comprised a fortified acropolis and a walled lower town. Fortified urban centers, chief among them Hazor, Lachish, and Megiddo, flourished in the south in the MBA (Burke 2018, 265–71, 287–8, 290–6). Burke's recent study (2018) of MBA fortifications from around the region demonstrates the interconnectedness of the urban centers throughout Syria-Palestine and the communication of ideas and practices over a wide area. Solid mudbrick walls 3–4 m wide with stone foundations were built on large freestanding earthen ramparts, or a glacis (an artificial slope created of earth on existing mound or hill, the outer slope covered with lime). There is clear evolution of the massive gateways from the four-pier bent axis structures of MBIIA gate to the standard four- and six-pier gate in MB IIB. Also common throughout the region in the MBA and LBA was the migdol (tower) temple.

The fortified towns of the MBA and LBA were dominated by monumental impressive palaces, located on the upper citadel in Syria. The east Syrian palaces, most famously that of Zimri-Lin at Mari with its many courtyards, demonstrate Mesopotamian influence. In western Syria, including Ebla and Alalakh, a different architectural tradition develops asymmetrical palaces, with hypostyle halls, royal burial vaults (hypogaea), and the widespread use of basalt orthostats and cedarwood columns. Several MB palaces, Qatna and Alalakh in the north and Kabri in the south, were decorated with Aegeanizing wall paintings (Brysbaert 2008). At Alalakh there is a prototype of the bit hilani type palace, comprising a wooden-pillared portico at the entrance to reception room approached by a broad but low flight of steps. The LBA palace at Ugarit combined the traditions of east and west Syria; covering an area of around 1 ha and protected by a sloping glacis, it comprised some 100 rooms, courtyards, a garden, and intramural dressed royal tombs. The palaces identified in the south in the MB-LB, for example, at Hazor and Megiddo, tend to be smaller than their Syrian counterparts, but similar in overall design. Patrician houses, large structures with open courtyard, a pillared hall, storage rooms, and an upper floor are common in LBA sites in the southern Levant, such as at Tell Beit Mirsim.

Interpretations of urbanization and state formation are closely intertwined within narratives of external (imperial) influences from the pristine states of Egypt and Mesopotamia. The earliest evidence for colonial activity dates to the late fourth millennium BCE and is usually attributed to trading endeavors for raw materials. Egyptian Dynasty 0 colonies have been identified in the southern Levant in EB I, at sites such as En Besor, Arad, and Tell Sakan, apparently established to control trading activities (Van den Brink and Braun 2003). These are characterized by Egyptian style architecture, locally made Egyptian pottery, and sherds marked with a serekh (one of the Egyptian king's royal names written inside a palace façade), including several Narmer serekhs (Braun 2009). Several fortified Late Chalcolithic sites on the Syrian Euphrates have been identified as Uruk colonies on the basis of their southern Mesopotamian architecture, material culture (including the characteristic bevel-rimmed bowl), and bureaucratic paraphernalia (numerical tablets, bullae, and seal impressions) (Stein 2014). The best known of these is Habuba Kabira. These "colonies" represent the earliest documented territorial expansion by the Egyptians and the city states of ancient Mesopotamia into the Levant; while both examples provide evidence for administrative activity and a need for protection, in the form of fortifications, it is not possible to demonstrate imperial governance over the wider hinterland.

The LBA (c.1600/1550–1200) can be characterized as an age of Empire, with three great powers competing over the territory of Syria-Palestine: Egypt, Mittani, and the Hittites. A destruction horizon separating MBA and LBA strata at several sites in the southern Levant has commonly been attributed to 18th Dynasty Egyptian military activity following the expulsion of the Hyksos (Toffolo et al. 2014, 240–1). There was an apparent urban decline in the southern Levant in the LBA, and the region is characterized by smaller city-states, a change that has been attributed to Egyptian imperial activity. The main phase of Egyptian expansion was in the Thutmosid period in LB I. Both Thutmosis I and III reached the Euphrates in their military campaigns, but for the most part, Egyptian military and imperial activity centered on the southern and central Levant. Here a number of Egyptian residencies and military establishments have been identified dating to LB II (19th Dynasty), including Beth Shan, Tel Rehov, and Deir el-Balah. These are characterized by distinctive Egyptian architecture and locally made Egyptian pottery. There are also numerous examples of Egyptianizing clay coffins at sites such as Beth Shan, Deir el-Balah, and Lachish, which have been attributed to burials of Egyptian officials (Steel 2018, 21–2). Although Egyptian officials were undoubtedly active in the southern Levant, for the most part, imperial rule was mediated via the local petty rulers, many of whom are recorded in the Amarna letters (Moran 2000).

The kingdom of Mittani was a significant power in the northern Levant during the earlier LBA (fifteenth to mid-fourteenth centuries). Their power base was the upper Khabur plains, and their capital of Washukanni has been identified with Tell Fakhariyah. Archaeologically, Mittani remains elusive, their only clear cultural markers being the distinctive Nuzi ware and Mittani-style cylinder seals (Akkermans and Schwartz 2003, 329). They were superseded in the late fourteenth century by the Hittites, under the reign of Šuppiluliuma I (c.1350 BCE), whose power base was Hattusas (modern-day Boğazköy) in the central Anatolian plateau. The Hittites controlled the region through local vassal kings; materially, they have left little mark in the archaeological record and physical evidence for their domination primarily comes from textual sources, as, for example, the Hittite seals, bullae, and cuneiform texts from the archives Ugarit (Yon 2006).

Empire continued to shape the Levant during the Iron Age, although this has not received the same attention in the archaeological literature. The geopolitical landscape of the Early Iron Age was greatly transformed following the collapse of the LBA centers c.1200 BCE (Ward et al. 1992; Yener 2013). Other than Sheshonq I's attack on the southern Levant, c. 925 BCE, recorded on a stele fragment from Megiddo and on the Karnak Temple List (Kitchen 1986: 432–47), Egypt had ceased to be a major power in the region. The

major imperial power that emerged in the region in the first millennium was Assyria. Between the reigns of Tiglath-Pileser III (745–727 BCE) and Ashurbanipal (668–627 BCE), the Assyrian rulers launched successive attacks on the major cities of the Levant, taking prisoners and tribute, which they recorded on the walls of their palaces. State formation continues to be a theme in the Iron Age, as, for example, Moab in Transjordan in Iron II (Routledge 2004).

The key debates shaping Iron Age research in the southern Levant have been migrations and ethnicity or identity (Yasur-Landau 2014; Finkelstein 1988). These narratives are embedded in archaeological interpretations of the relationship between material culture and cultural identity and also in more nuanced understanding of social praxis and lifeways. A key example of this is the identification of the characteristic bichrome Philistine pottery in Iron I strata with a migrant Aegean population (Dothan 1982; Yasur-Landau 2014). This debate is now increasingly underpinned by understandings of trans-culturalism (Hitchcock 2011) or cultural hybridity and how this resulted in the reinvention of Aegean architecture, especially hearth buildings at Tel Qasile and Tel Miqne (ancient Ekron), religious practices, and diet, in particular the consumption or otherwise of pig. Finkelstein (1988) has explored the formation of early Israelite identity (or ethnicity). He opposes the traditional view, strongly influenced by biblical narratives, that the rise of early Israel in the first millennium BCE resulted from a population shift from the Canaanite lowlands into the highlands during Iron I. Instead, drawing upon a detailed examination of the archaeological record (architecture, pottery, and foodways) in the highlands both east and west of the River Jordan – which he situates within a longue durée understanding of fluctuations in settlement patterns in the wider region – Finkelstein argues for population and cultural continuity in the highlands between LBA and Iron I, suggesting that the Israelites were settled pastoral nomads. Iron I is poorly known in Syria, but by Iron II, new political groupings have emerged in the region, chief among them the Neo-Hittites in the north and the Phoenicians in the central Levant. Examples of the bit hilani palaces are attested at Zincirli, Alalakh, Carchemish, and Tell Halaf (Akkermans and Schwartz 2003, 368–73); monumental architecture at these sites is adorned with sculptures of lions and sphinxes and relief carvings demonstrating a strong Hittite influence.

Despite the perceived focus on impressive monumental structures (fortifications, palaces, and temples) and as a corollary emphasis on social complexity in the literature (as discussed above), there are numerous examples of well-excavated domestic structures throughout the region. Accordingly, there is a growing interest in social archaeologies informed by theoretical perspectives to explore daily life and the activities of the ancient populations of the regions. This has resulted in nuanced discussions of household archaeology, which focus on how people created and negotiated domestic spaces, looking in particular at the material residues of behavioral patterns (Yasur-Landau et al. 2011; Foster and Parker 2012). Equally, there has been greater interest in gender, with an emphasis on the social and economic roles of women within and beyond the household (Meyers 2003; Budin and Turfa 2016). Issues of memory, identity, and ancestor cult have been explored at several EBA sites, including Bab edh-Dhra in Transjordan (Chesson 2007) and Umm el-Marra (Schwartz 2007) and Tell Banat (Porter 2002) in Syria.

International Perspectives

A key theme in recent scholarship has been interconnections within and beyond Syria-Palestine (e.g., Aruz et al. 2013), in particular as a result of flourishing trade routes connecting the region not only to Egypt and Mesopotamia but equally to the Mediterranean world. Access to the exotic shaped and defined the material culture and identities of the communities of the region. Particularly close were the social and economic ties binding Byblos and Egypt, a relationship which stretches back to the EBA. These are perhaps best

illustrated by the eight rock cut shaft tombs identified as royal tombs, contemporary with the Egyptian 12th Dynasty. There was selective adoption of certain Egyptian features in these tombs, including personal adornment, faience fragments from an Egyptian-style coffin, and the use of Egyptian hieroglyphs and titles, suggesting detailed knowledge of Egyptian practices.

Large quantities of imported Cypriot and Aegean pottery found at sites along the Levantine coast, between Ugarit in the north and Tell el-'Ajjul in the south and inland as far as Transjordan, attest to the importance of maritime trading connections during the LBA. This was apparently available to the mercantile classes and was readily incorporated in social practices within settlement and funerary contexts throughout the region (Steel 2012). These vessels were exchanged in mercantile trade (also evidenced by several shipwrecks in the Mediterranean). High status gift exchange between rulers in the LBA is illustrated by the so-called International Style (Feldman 2008). This refers to portable luxury objects found in elite contexts, which were made of valued materials such as ivory, alabaster, gold, silver, and faience and characterized by a mix of forms and motifs from the Aegean, Egypt, and the Levant so that their places of origin are unclear. Examples from the Levant include faience animal cups (bibru) from Ugarit and Hazor and the Megiddo ivories found in the twelfth-century palace.

Traditionally, it was accepted that following the collapse at the end of the Bronze Age, there was a breakdown in maritime trade until the eighth century, a period that has been described as a Dark Age. Today there is clear evidence that the Levant and Cyprus continued to be involved in exchanges throughout this period. The adoption of iron has been demonstrated to be the result of the close cultural and economic relations between Cyprus and the southern Levant (Philistia) in the twelfth century (Sherratt 1994). A more detailed knowledge of the Phoenician ceramic typology, based on soundings at Tyre, clearly demonstrates that the earliest phase of Phoenician expansion west to Cyprus dates to the eleventh century (Bikai 1987), which is reiterated by evidence for Phoenician activity in the Aegean as early as the tenth–ninth centuries. By the eighth century, the cities of Sidon, Tyre, and Byblos were establishing colonies in the west Mediterranean in their search for metals to supply the Assyrian empire. Evidence for Greek trading, and possibly even colonial, activity in the northern Levant is more controversial. Woolley famously identified the port site of Al Mina (Luke 2003) as a Greek (Euboean) colony, based on the large quantities of Greek pottery (primarily decorated drinking equipment) found there from the late eighth century. The material habitus of the site (architecture, burials), however, does not support resident Greeks, and current opinion is that the pottery represents imports brought by enterprising Phoenician (?) traders.

Future Directions

To date our understanding of the archaeology of Syria-Palestine has been based on meticulous recovery and analysis of the material remains. Ceramic typologies, architectural studies, stratigraphic sequences, and faunal analyses, to name but a few, form the bedrock of the debates and narratives outlined above. Interdisciplinary research, drawing on developments in biological and chemical sciences, is increasingly playing a significant role in archaeological research, enhancing our understanding of the Bronze and Iron Ages in the region. Harvey Weiss' (2015) ongoing exploration of the dramatic climatic events at the end of the third millennium BC is particularly relevant to current concerns about climate change in the Anthropocene. Archaeological survey is being enhanced by the application of online satellite imagery, which facilitates the mapping of environmental features for a more nuanced understanding of settlement patterns. This has been used for example to explore pastoral herding patterns in southern Syria (Ansart et al. 2016). DNA analysis is providing more information about ancient populations. Most recently, a study of ten skeletons from the Philistine site of Ashkelon has helped to resolve the issue of

population movements at the end of the Bronze Age (Feldman et al. 2019). Results indicate that the DNA of twelfth-century skeletons had similarities with ancient Cretan DNA. There was, however, limited genetic impact on the Iron Age population at the site, and there is virtually no trace of the European DNA in skeletons dating to the tenth–ninth centuries. These are just a few of the scientific developments transforming Syrian-Palestinian archaeology in the early twenty-first century.

The Archaeology of the ʻOpunohu Valley, Society Islands, Eastern Polynesia

Jennifer G. Kahn
Anthropology Department, College of William and Mary, Williamsburg, VA, USA

State of Knowledge and Current Debates

The ʻOpunohu Valley, located on the north shore of Moʻorea (Fig. 1), in the Windward Society Islands, Eastern Polynesia offers a number of advantages for archaeological research. The valley has a long and intensive history of archaeological field research, offering detailed data on settlement patterns in the Society Islands and within the broader regional context of Central Eastern Polynesia. The valley has well-documented and well-preserved surface architectural remains dating to the prehistoric-protohistoric period. A robust radiocarbon and U-Th chronology illustrates that most surface structural components date to c. AD 1350–1800, permitting diachronic analyses of change through time. Finally, oral traditions, ethnohistoric texts, and archaeological data demonstrate the central importance of the ʻOpunohu as a highly productive "core" with extensive evidence for residential, ceremonial, and agricultural use, making it an ideal location for multiscalar analysis of social complexity in chiefdom level societies. After discussing the geographic context of the valley and the history of archaeological research, I will turn to a synthesis of ʻOpunohu Valley settlement patterns, agricultural intensification and human-environmental landscape change, household arhaeology and inequality at the microscale, monumental architecture and macroscale patterns of social complexity, and demography.

Geographic Context and Natural Resources

The ʻOpunohu Valley is the largest valley on Moʻorea, c. 1500 ha in area (Figs. 1 and 2). The valley has three broad physiographic units: the valley bottom, the upper valley, and the mountain slopes and ridges which form the edge of the valley. The lower valley includes c. 800 ha of flat floodplain with rich soils suitable for cultivation. The upper valley begins roughly 1200 m inland and extends to the base of the mountains which reach over 700 m. The upper valley is characterized by a series of hills and water-fed valleys; much of this terrain has high-quality soils amenable to dryland and wetland cultivation. In terms of socioeconomic organization, the upper valley is divided into the Amehiti and Tupauruuru sections which formed traditional Māʻohi sociopolitical districts at the time of European contact in 1767. Tupauruuru has less pronounced relief than Amehiti or the Middle sector (Fig. 1), and

The Archaeology of the ‘Opunohu Valley, Society Islands, Eastern Polynesia, Fig. 1 Map of Mo‘orea, Society Island and location of the ‘Opunohu Valley

The Archaeology of the ‘Opunohu Valley, Society Islands, Eastern Polynesia, Fig. 2 Photo of the Tupauruuru District, ‘Opunohu Valley

these topographic differences resulted in somewhat divergent precontact settlement patterns.

In the ‘Opunohu Valley, permanent rivers and streams and high rainfall offered rich natural resources for the development of highly productive agricultural systems. The upper valley has branching rivers that flow into a single channel in the lower valley before discharging into ‘Opunohu Bay. Rainfall is abundant but varies with elevation. While there are no figures for rainfall at the valley bottom, comparisons with other nearby valleys (Lafforgue and Robin 1989) suggest c. 2500 mm of rain per year (Lepofsky 1994). The upper valley receives over 3200 mm per year, with two thirds of precipitation falling during the wet season. The foot of the mountains receives between 3500 and 4000 mm of rain per year (Lafforgue and Robin 1989; Météo-France 2004).

Traditional History

Traditional accounts suggest shifting sociopolitical configurations in the ‘Opunohu Valley through time. In early prehistory, no single district chief had authority over the others on the island of Mo‘orea; at this time at least one district within the ‘Opunohu Valley was under control of the Atiro‘o clan (Adams 1976: 163–165). A century or so prior to European contact, the then dominant Atiro‘o clan in the ‘Opunohu were overthrown by the powerful Marama lineage from Ha‘apiti (Adams 1976). The Marama line split the valley into two sociopolitical districts, Tupauruuru to the east and Amehiti to the west (Fig. 1). By the time of Cook’s voyages, the valley was the seat of a prominent Marama chief named Mahine (Green et al. 1967: 220–221; Oliver 1974: 1204–1205). Between 1774 and 1777 increasing conflicts developed between the paramount chiefs of Tahiti and Mo‘orea, after Mahine opposed leaving his title to an heir of the ruling Pomare line from Tahiti. Thereafter during the protohistoric period, the unified districts on the north shore of Mo‘orea, including the ‘Opunohu Valley, formed a chiefdom made up of seven large districts under the control of the Pomare clan (Handy 1930: 80–82). A chant recorded by Murau refers to the Amehiti and Tupauruuru districts during the Marama rule:

Come, oh come to your districts Tupauruuru and Amehiti,
To see the big canoe without an outrigger.
Its rowers are fair as the white clouds!
But Marama, the arii, *replied:*
No my children, no, I will not come. Take from me good counsel:
Curiosity has ever a bad temper,
Fair clouds and dark clouds can never long agree.
We have no better teacher than the storm. (Handy 1930: 82)

History of Archaeological Research

Kenneth P. Emory of the Bernice P. Bishop Museum arrived in the Society Islands in January 1925 and began a surface survey, primarily of large temple sites (*marae*). In his monograph, *Stone Remains in the Society Islands* (1933) Emory describes over 240 structures throughout the archipelago, but to a large extent his survey focused on coastal contexts. In the ‘Opunohu Valley, Emory recorded only three temples, a few house sites with pavements, and a smaller unnamed structure (Emory 1933: 106–107, Figs. 70 and 71).

Green’s pioneering settlement pattern research in the ‘Opunohu (Green 1961; Green et al. 1967) resulted in the mapping and description of over 63 dwelling structures, 111 probable habitation terraces, 145 religious structures (*marae* and shrines), and 77 agricultural complexes (Fig. 3; see Green and Descantes 1989); the latter often incorporated large clusters (>10–30 in number) of stone faced terraces. Green developed a culture historical sequence and understanding of site function with limited excavations at five site

Site Type	Count
Dwelling Structures with Curbstone Outline	63

Specialized- Council Meeting Platforms	5
Specialized- Archery Platforms	3
Religious Structures (Temples and Shrines)	145
God Figures (*ti‘i*)	18
Agricultural Complexes	77

The Archaeology of the ‘Opunohu Valley, Society Islands, Eastern Polynesia, Fig. 3 Roger Green Site Survey Data, ‘Opunohu Valley

complexes, including work at five temples and six house sites (Green et al. 1967). Reanalysis of Green's original data (Cochrane 2002; Descantes 1990, 1993; Eddowes 1991) has emphasized ritual sites (*marae*), seriation, and the potential social dimensions of ceremonial architecture and the function of precontact house sites (Orliac 2000), while Green (1996) continued to document aspects of valley-wide settlement patterns.

Dana Lepofsky (1994), Lepofsky et al. (1996) augmented Green's survey by extensively recording the spatial contexts of irrigated and dryland agricultural terrace complexes in the ʻOpunohu Valley. In her expert analysis of Māʻohi ethnohistoric documents, she outlined 6 major cultivation subsystems (1994) and the economic uses of 47 major cultigens (2003). Her archaeological work in the upper ʻOpunohu Valley documented terraced agricultural complexes adjacent to the main rivers and stream branches in Tupauruuru (Lepofsky et al. 1992, 1996), while some limited survey, mapping, and excavation were completed in the Middle and Amehiti sectors. Lepofsky completed test excavations at eight agricultural complexes, seven in Tupauruuru and one in Amehiti. She also developed a radiocarbon sequence to refine the valley's settlement chronology and to delineate a sequence of agricultural intensification (Lepofsky 1995).

In order to parse out geochronological sequences of landscape formation and human use/modification, Lepofsky completed considerable archaeological and geomorphological work in the lower ʻOpunohu Valley (Lepofsky 1994). Twenty-one back hoe trenches on the lower valley floor and 6 stream profiles in the upper valley were stratigraphically analyzed. Laboratory analyses included grain size analysis and X-ray diffraction of sediments, as well as wood charcoal identifications, to investigate long-term human-environmental interactions and their relationship to landscape use and agricultural intensification. Lepofsky's work continues to serve as the only detailed analysis of Māʻohi agricultural practices in the precontact period.

Finally, the author has completed multi-scalar archaeological analysis in the ʻOpunohu Valley since 1999. This work has included continued survey, mapping, and settlement pattern analysis in the Tupauruuru, Middle, and Amehiti sectors (Kahn 2005a, 2009, 2016a). A major program of household archaeology and landscape scale analysis saw the excavation of 13 precontact house sites, 19 terraces (including terraces fronting temples and probably habitation flats), three *paepae* (upraised stone platforms), 2 council platforms, 11 temple sites (*marae*), and 3 shrines (Kahn 2003, 2007, 2009, 2013, 2016b; Kahn and Kirch 2013, 2014). Dedicated radiocarbon dating of newly excavated sites and archived samples from Green's original excavations has predominately focused on short-lived species lacking inbuilt age to develop a robust settlement chronology (Kahn 2006, 2010, 2011). The use of both radiocarbon dating and more precise U-Th dating of corals incorporated into temple architecture has resulted in a refined chronology for temple construction sequences (Kahn 2011; Kahn and Kirch 2011, 2014; Sharp et al. 2010). Finally, newly excavated agricultural sites (Fig. 4) microfossil and wood charcoal identifications, and landscape scale analyses, including additional geomorphological work in the valley bottom, have advanced our understanding of Māʻohi agricultural practices and human-induced landscape change (Kahn et al. 2014, 2015; Kahn and Ragone 2013).

Settlement Pattern Analysis

Based on his original survey data, Green argued that an average to low density of surface remains were found in the Amehiti sector (Green 1996: 211), in contrast to the dense patterning of settlements found in Tupauruuru. Following this, Green posited that a dense population of ritual and social elites occupied the dominant ritual and residential sector of Tupauruuru. Low-, moderate-, and high-status residences are interspersed throughout this district, along with major agricultural complexes. Green found more temples (*marae)* and particularly larger and more elaborate *marae* in Tupauruuru sector. This sector also and more "specialized high-ranking structures," including large round-ended assembly houses, large raised assembly platforms (council platforms), and archery platforms, the latter were

The Archaeology of the ‘Opunohu Valley, Society Islands, Eastern Polynesia, Fig. 4 Plan View of Agricultural Complex ScMo-330 with Barrage Terraces, Dryland Terraces, and Wetland (Irrigated) Terraces. Note that ScMo-330 is an inset in the larger landscape map found in Fig. 6

used for elite sport (Green 1961; Green et al. 1967: 224–225). Green (1996) interpreted the settlement pattern data as representing a more complex social hierarchy in Tupauruuru than Amehiti, as site density and site types varied considerably between the two sectors.

While the ‘Opunohu Valley has a long history of archaeological survey, site inventory has

largely focused on the eastern Tupauruuru sector, with survey data lacking for the Middle sector and quite limited for the Amehiti sector. Green's original Amehiti survey was brief, overall less intensive than that carried out in Tupauruuru, and focused largely on the lower valley flat. Lepofsky argued that Green's survey adequately recorded all site types within Amehiti (see Green 1996: 213–214; Lepofsky 1994: 144–145), yet this must be qualified as referencing lower Amehiti, as neither Green nor Lepofsky worked substantially in the upper sector. Subsequent limited archaeological survey in the upper Amehiti and upper Middle sector has documented that there are indeed fewer *marae* in these parts of the valley, yet six new *marae* complexes were located along two ridges in upper Amehiti (Kahn 2005b). It seems likely that additional survey will uncover more *temple* complexes in these understudied portions of the valley.

Preliminary analysis of the Amehiti survey data illustrates that certain areas have a moderately high density of habitation sites, somewhat higher than previously noted (Kahn 2005a; contra Descantes 1990; Green 1996; Lepofsky 1994). The Amethi district has relatively dense clusters of low-status habitation zones and some presence of moderate-status houses of oval-ended form, including sites that were used for specialized activities (Kahn and Kirch 2013). Amehiti *marae* tend to be small and have varied architectural plans. Some Amehiti temples cluster with important agricultural complexes or important water sources (springs), a pattern not previously recorded for the valley (Green 1996: 220, after Descantes 1990: 124), nor examined in other *marae* studies in the archipelago (Cochrane 1998, 2002). These data suggest that at least some Amehiti *marae* were likely used in agricultural rites or fertility ceremonies. Amehiti house sites also tend to be situated in different locales than Tupauruuru house sites. Finally, while Amehiti house terraces can reach the size of Tupauruuru habitation terraces, they often lack high-quality architectural construction or other signs of high status.

While the Middle sector has seen the most modern development and the least archaeological survey, agricultural sites are found here in continuous association alongside all usable areas of the main river (Kahn 2009; Lepofsky 1994: 143) suggesting a substantial precontact population. A reconnaissance survey of three ridges flanking the major river and its tributaries recorded a moderate density of agricultural complexes and residential sites, ranging from dispersed to nucleated settlements (Kahn 2009). The majority of recorded sites include agricultural complexes or water control features (55%), while aggregated residential and agricultural sites comprise 27% of the total sites surveyed. Of note, temples and shrines are lacking in this sector, and only a small percentage of surveyed sites have a probable ceremonial function (4.3%). Residential features were small and lacked elaborate architecture, even in contrast to Amehiti where most residential architecture was of moderate elaboration.

Taken as a whole, the ʻOpunohu Valley settlement pattern data suggest significant differences in the three major zones of the valley, some of which are likely related to topography, others of which are related to social organization. All sectors have high densities of precontact agricultural sites, suggesting substantial labor inputs to modify the landscape and increase agricultural productivity. Tupauruuru has the highest number of house sites, with a range of sizes and elaboration. Of the three sectors, Tupauruuru has the clearest evidence for an elite, high-status population, with substantial numbers of large, elaborate house sites and aggregated ceremonial complexes. In contrast, Amehiti has a moderate amount of residential sites and temple sites, both of which tend to be of moderate size and elaboration, while the Middle sector tends to have smaller low-status house sites and lacks ceremonial architecture.

Current ʻOpunohu Valley settlement pattern data suggest significant status differences among the three sectors, with Tupauruuru serving as a mixed elite to low-status sector with substantial evidence for residential, agricultural, and religious activities; Amehiti serving as a moderate- to low-status sector, with substantial evidence for residential, agricultural, and religious activities; and the Middle region serving as a low-status sector with substantial evidence for agricultural

and, to a lesser extent, residential activities. These data are supported by the spatial distribution of aggregate site complexes, defined as clusters of two or more elaborate temple sites, often in association with shrines, specialized-use house sites, and other high-status specialized structures, including archery platforms and council meeting platforms. Extensive aggregate clusters with elaborate house sites, specialized community structures, and monumental temples have been identified as ritual-political centers, and their spatial locations can be used as a proxy for status hierarchies (Green 1961) and the development of a ruling class of high-status elites (Kahn 2005b, 2010, 2011; Kahn and Kirch 2014). That four of the five currently identified ritual centers are found in Tupauruuru, with only one in Amehiti and none in the Middle sector, supports the interpretation that high-status elites largely censtered their settlement and religious practices in the Tupauruuru sociopolitical district. In fact, three of the five ritual centers are found in close association to one another at mid-elevations in the Tupauruuru sector (Fig. 5), highly suggestive of ritual ceremonies, competitive feasting, and other events hosted by high-status chiefs.

Agricultural Intensification and Human-Environmental Landscape Change

Archaeological survey has documented three main forms of cultivation systems in the ʻOpunohu Valley: rare wetland irrigated complexes with stone faced terraces along river and stream banks; and the more common barrage pondfields located in slow-moving or intermittent streams in addition to rain-fed dryland complexes with stone faced terracing (Lepofsky 1994; Lepofsky and Kahn 2011; Kahn 2005a). Geomorphological data from the lower valley indicate that soon after island colonization c. AD 1000, the Māʻohi cultivated coconuts and probably other crops on the ʻOpunohu Valley bottom (Fig. 7; Lepofsky et al. 1992, 1996). At the same time, slash and burn practices in the upper valley resulted in massive erosion of sediments into the valley bottom.

The Māʻohi began to construct terraced agricultural complexes in the valley c. AD 1250 (Lepofsky 1994; Lepofsky and Kahn 2011). This represents the first period of agricultural intensification, where significant labor inputs went into constructing permanent agricultural infrastructure, also known as landesque capital intensification (Brookfield 1972, 1984). Excavation data and wood charcoal analysis indicate that that the wetland terraces, rain-fed terraces, and barrage pondfields were likely used to cultivate taro and other root crops. Dryland terraces supported tree crops (breadfruit, Tahitian chestnut), root crops (yams, taro), and other economically important crops such as banana. By AD 1350–1450 many inland terrace complexes had been constructed in the ʻOpunohu Valley, consonant with an intensive period of house and temple construction. Some dryland terraces for tree cropping extended into more marginal lands at high elevations, suggestive of both elite demands for surplus and commoner desires for daily autonomy (Lepofsky and Kahn 2011). A second period of agricultural intensification occurred c. AD 1600, where new upland agricultural complexes were constructed astride large ritual-political centers, all of which were likely under elite control (Kahn 2017; Kahn and Kirch 2014; Lepofsky and Kahn 2011).

Household Archaeology and Inequality at the Microscale

Prehistoric habitation sites in the ʻOpunohu Valley are ubiquitous, with 132 rectangular and round-ended house sites outlined by curbing stones in addition to c. 300 pavements and "living flats" lacking curbstone outlines (Green et al. 1967; Green and Descantes 1989; Kahn 2003, 2005a, b, 2007, 2016c; Kahn and Kirch 2003, 2013; Oakes 1994). Excavations have now been completed at seven residential/ritual complexes, with 24 probable house sites excavated. The majority of ʻOpunohu household archaeology projects have included large block excavations or extensive horizontal excavations, facilitating recovery of subsurface features and artifacts and allowing for precise interpretations of household status and house function (Kahn 2017, 2018).

Data from the corpus of excavated ʻOpunohu Valley house sites indicate change through time at the community level in terms of household rank and

The Archaeology of the ‘Opunohu Valley, Society Islands, Eastern Polynesia, Fig. 5 Settlement Pattern Base Map, Segment of Tupaurauru District, ‘Opunohu Valley

The Archaeology of the ‘Opunohu Valley, Society Islands, Eastern Polynesia, Fig. 6 Example of Amehiti district surface architecture including a Ridge with House Sites, Ceremonial Sites, and Agricultural Complexes

status and occupational specialization. The construction of the first ‘Opunohu Valley house sites begins c. AD 1350, about 100 years after the construction of the first major formalized agricultural complexes. At this time, house sites already exhibit a diversity of sizes, types, and architectural elaboration, signaling that status differences between elites and commoners were materialized at the local level by the fourteenth century AD (Fig. 6; Green 1996; Kahn 2005a, 2007, 2016c).

An ongoing concern lies in differentiating residential house sites (sleeping houses) from specialized-use house sites that were associated with craft production, communal activities, and occupational specialists (Orliac 2000). ‘Opunohu Valley studies have found that the number and type of ancillary buildings around house sites, and the placement and timing of houses on the landscape, are indicators of house site function (Kahn 2005b). House size and form (round-ended or rectangular) alone are not sufficient to determine house status or site function (Kahn and Kirch 2011, 2013). Elaborated architectural elements and certain architectural features, including basalt uprights, well-constructed paved areas adjacent to the house structure, and placement of the house on an elevated and raised terrace, are good indicators of house rank or specialized-use sites. Evidence for daily activities, such as cooking, food storage, and stone tool production and use (Kahn 2005a, 2007, 2016c; Kahn and Kirch 2013; Oakes 1994), are equally important for identifying house function or status.

In the ‘Opunohu Valley a pronounced shift in settlement patterns and house use are signaled by the construction and use of large and elaborate

The Archaeology of the ‘Opunohu Valley, Society Islands, Eastern Polynesia, Fig. 7 View of a specialized-use house, e.g., a large round-ended meeting house. “Capt. Samuel Wallis of HMS Dolphin being received by the Queen of Otaheite, July 1767” engraving from Account of voyage round world in years between 1766 and 1768 by Samuel Wallis

specialized house structures c. AD 1550–1650 (Fig. 7). Notable architectural differences and spatial patterning emerge, differentiating residential houses, or those houses used as sleeping houses, from communal houses used for public meetings and other types of activities and from specialized-use houses used for diverse activities, most notably ritualized production (Kahn 2003, 2005a, 2016c; Kahn and Kirch 2013; Lepofsky and Kahn 2011). Communal and specialized house sites are often associated with the highly sacralized ritual-political centers, illustrating how rank and hierarchy were materialized on the Mā‘ohi landscape (Fig. 8). Communal house structures and specialized house structures served as residences and craft locales for high-status occupational specialists and ritual practitioners (Kahn 2015). Ultimately, the construction and use of such house sites not only played into existing sociopolitical hierarchies but created new avenues for the expansion of elite power (Kahn 2005a, 2007, 2015).

Finally, studies of household material culture and their relationship to household status in the ‘Opunohu Valley have highlighted that both artifact assemblages and subsurface feature constellations differ between elite and commoner house sites. There is substantial variation in production and consumption activities between house sites of differing rank. Such patterns are expressed in the presence of adze production versus adze consumption activities; the size, layout, and form of cooking features; the frequency of food storage pits and other signs of surplus production; and the use of sacred and economically important woods in house post construction (Kahn 2016c; Kahn and Coil 2006; Oakes 1994). Specialized-use house sites have greater numbers of stone tools produced from off-island sources than residential house sites (Kahn et al. 2013), suggesting socio-ritual elites utilized long-distance trade networks as one of many strategies for consolidating their power and authority.

The Archaeology of the ‘Opunohu Valley, Society Islands, Eastern Polynesia, Fig. 8 Map of ScMo-106, an Aggregate *Marae* Ritual-political Center

Monumental Architecture and Macroscale Patterns of Social Complexity

There are two forms of religious architecture in the Society Islands. Shrines or small pavements with uprights and god figures (*ti‘i*) were contexts for individualized religious rites (Kahn 2016d). Temples (*marae*) or stone enclosures elaborated with rows of uprights, backrests stones, and altars were contexts for larger familial and community rites (Fig. 8; Kahn and Kirch 2014). Two hundred and twenty-five temples and shrines have been recorded in ‘Opunohu Valley archaeological surveys; 26 of these temples and shrines have been test excavated or dated via 14C or U-Th (Green et al. 1967; Kahn 2010, 2011; Kahn and Kirch 2013, 2014).

Archaeological studies have documented that Mā‘ohi temples became elaborated through time, both in terms of size and form. The first ‘Opunohu Valley temples were constructed c. AD 1350

The Archaeology of the ʻOpunohu Valley, Society Islands, Eastern Polynesia, Fig. 9 *Marae* Mahine, ʻOpunohu Valley. This war cult *marae* has worked stones used in the wall and altar construction. The *ahu* (altar) has a stepped construction

(Kahn and Kirch 2013), at the same time that house sites of a range of sizes and elaboration were also constructed for the first time. These simple *marae* include elevated pavements with rows of uprights, but lack upraised stone altars like the later, more elaborate forms. This first stage of temple construction is associated with the major inland expansion when residences and major agricultural complexes are also constructed. Interestingly, the first temple sites often are constructed at the same time as house sites of moderate status and agricultural complexes along major rivers and springs. In effect, temple construction appears to serve as a physical marker for claims to land and important resources.

Around AD 1450 temple forms become more elaborate (Kahn 2011; Kahn and Kirch 2014; Sharp et al. 2010). Not only are *marae* larger in size, but they are constructed with fancier architectural features. These include prismatic basalt capping stones, formal entryways, paved courts, and upraised stone altars at one end. A second stage of *marae* elaboration commences c. AD 1600, when coral facings were placed on stone altars and clusters of temples were arranged into aggregate *marae* clusters that were used as socio-ritual centers (Fig. 8; Kahn 2011; Kahn and Kirch 2014; Sharp et al. 2010). Following this, c. AD 1700 altars are considerably elaborated with the use of cut and faced coral blocks in a stepped fashion. The final stage of temple elaboration comes with the construction of multitiered altars (stepped *ahu*) and the use of pecked rounded stones in the enclosure walls or the altar (Fig. 9; Kahn 2010).

The ʻOpunohu Valley has a robust temple chronology clearly indicating the amplification of temple architecture and temple size through time, particularly an increase in the size of enclosures and the height and decorative treatment of altars. Truly monumental *marae* with elaborate stepped *ahu* and sculpted stones are used in the final period of elaboration just prior to European contact. The ʻOpunohu Valley monumental architecture sequence illustrates the ever-increasing role that ideology and religious rituals played in supporting the socioeconomic and political power of Māʻohi ruling chiefs at the community level. Data from ʻOpunohu Valley house sites and ceremonial complexes, namely, highly sacred, isolated ritual-political centers, replete with large temples and specialized houses for craft specialists and other occupational specialists such as priests, become ubiquitous c. AD 1600 onward, and serve as physical signs of increasing political centralization at the community and regional level (Fig. 10; Kahn 2016a, c; Kahn and Kirch 2014).

Date	ʻOpunohu: Agricultural Complexes	ʻOpunohu: House Sites	ʻOpunohu: Monumental Architecture	Archipelago-Wide Sequence
AD 1650-1750	Expansion and intensification of agricultural systems, often near ritual-political centers	Increased feasting, increased ritual production at specialized meeting houses; Round-ended (elite) houses, rectangular (commoner) houses	ʻOro style *marae* with worked stones, stepped *ahu* (coral blocks)	Classic Phase
AD 1600	Expansion and intensification of agricultural systems, often near ritual-political centers	Specialized meeting houses and ritual houses, often in association with ritual centers; Round-ended (elite) houses, rectangular (commoner) houses	Aggregate *marae* clusters in ritual-political centers, Megalithic *marae* with elaborate *ahu* (coral facing)	Classic Phase
AD 1450	Extensive agricultural complexes and mixed swidden in upper valley	Round-ended (elite) houses, rectangular (commoner) houses	Larger, more elaborate community level *marae* (*ahu*, entry way)	Late Expansion/ Development Phase
AD 1350	Extensive agricultural complexes and mixed swidden in upper valley	Round-ended (elite) houses, rectangular (commoner) houses	Simple family *marae* (no *ahu*), shrines	Early Expansion/ Development Phase
AD 1250	Slash and burn on hillslopes, erosion onto valley floor	---	---	Colonization Phase
AD 900-1000	Cultivation of valley floor (coconuts)?	---	---	Colonization Phase

Demography

The ʻOpunohu Valley is the only locale in the Society Islands where archaeologists have used archaeological data to develop precontact estimates for human population. Like other contexts in Polynesia and Oceania, precontact human population estimates are difficult to ascertain. European contact brought a mass of introduced diseases and sexually transmitted diseases previously unknown to Pacific Islanders who lacked immunities to Old World diseases. The first historic censuses were commonly completed 40 years or more after contact, after periods of devastating population loss. Thus, archaeological data provide a key dataset for estimating precontact populations, as do early European estimates prior to the devastating population losses in the later post-contact period.

For the island of Tahiti, where most European ships had the longest stays, early estimates range from 100,000 to 140,000 (Hamilton and Kahn 2007). Moʻorea estimates range from 20,000 to 40,000. Hamilton and Kahn utilized two approaches to develop precontact human population estimates for the ʻOpunohu Valley based on archaeological datasets. The first relied on two versions of the "house count" approach, where the number of house sites in the valley were counted, while house size and chronology were also taken into account. House count approaches provided population estimates of c. 1252, inhabitants for the valley. The second approach relied on estimating agricultural productivity in the valley and maximum carrying capacity, providing an estimate of c. 9750 persons. For various reasons, Hamilton and Kahn felt that the c. 10,000 population estimate for the ʻOpunohu Valley was the more likely estimate. Puelston and Tuljapurkar's population modeling (2008) took into account population age distributions, behavior, and technology and environmental constraints. Their analysis suggested that ʻOpunohu Valley agricultural yields could have been considerably higher (40%) than the Hamilton and Kahn carrying capacity estimate. This might suggest that late in prehistory, a considerable amount of agricultural produce was being converted into social production, notably foodstuffs used as gifts, offerings, exchange, and feasts that were then funneled into the chiefly political economy.

Archaeology of the Alps

Francesco Carrer
McCord Centre for Landscape, School of History, Classics and Archaeology, Newcastle University, Newcastle upon Tyne, UK

Introduction

The Alps are the most iconic mountain region of Europe, and archaeological research plays an important role in explaining how human communities have adapted to and transformed mountain landscapes and environments. Archaeological research in the Alps has a long tradition, which has been revived by recent exceptional discoveries, novel analytical approaches, and new research questions. Today the archaeology of the Alps includes a broad range of research themes, and it spans from the valley bottoms up to the highest summits. Archaeological data from the Alps contribute to understanding the prehistory and history of Europe and the Mediterranean, and they also have the potential to influence future development policies in the Alpine region.

Definition

The Alps are one of the most important mountainous regions of Europe (Fig. 1). They host some of the tallest summits of the continent (e.g., Mount

Archaeology of the Alps, Fig. 1 Relief map of the Alps. (By User: Perconte – Based on SRTM-Data, CC BY-SA 2.5, https://commons.wikimedia.org/w/index.php?curid=602322)

Blanc, 4810 m asl), they are bearers of unique heritage assets (e.g., the Dolomites and the prehistoric lake-dwellings, both part of the UNESCO World Heritage Site list), and they represent strategic reservoirs of freshwater and biodiversity. The Alps are a 1000 km mountainous arc, shared by eight countries (Austria, France, Germany, Italy, Liechtenstein, Principality of Monaco, Slovenia, and Switzerland), and they represent the second largest ecosystem in Europe. The size of this mountain region, its central position, and the fact that it's one of the most densely inhabited mountain areas in Europe (14 million people and almost 6000 different communities) explain its remarkable linguistic, cultural, and socioeconomic diversity. The Alps represent the geographical interface between Mediterranean and Central Europe, and it is widely acknowledged that they have played a key role in the history of the continent (Mathieu 2009). Therefore, the contribution of archaeological research in the Alps goes beyond the physical border of this mountain region and is critical for understanding the processes that influenced the evolution of European cultures and societies.

Socioeconomical aspects that characterize Alpine communities have been identified quite early by historians and geographers and led to the investigation of the adaptive processes behind their development. The starting point was the recognition of the ecological and accessibility constraints associated with mountain environments, which contributed to shaping the lifeways of Alpine peoples (Netting 1981). Although medium-size cities (>100,000 inhabitants) are not rare in the Alps (e.g., Grenoble, Trento, Innsbruck, etc.), the majority of people still live in small rural villages, which represent one of the most noticeable landscape characters in every Alpine valley. Until the second half of the twentieth century, the primary economic strategy associated with these villages was small-scale farming. Traditional Alpine farming is defined by the complementary exploitation of different ecotones at different elevations. Crop cultivation prevails at lower elevation, where the longer vegetative period and the better insolation make this farming activity cost-effective. Higher elevations are frequently associated with seasonal pastoralism, which exploits the open pastures above the timberline. The elevation of the timberline depends on climatic and microclimatic factors and is modified by human actions through different management activities (including slash-and-burn). Additional farming activities take place in the forested areas spanning between the permanently inhabited villages and the seasonally exploited upland pastures. These activities exploit the forest for different and non-mutually exclusive purposes: fuel, building material (timber), foraging, animal grazing, specialized cultivations (e.g., chestnut), haymaking, etc. Although all the aforementioned ecological zones are used by local rural communities, forests and pastures are less intensively exploited than the arable fields. Since forests and pastures cover over the 60% of the territory, game hunting represents an important complementary food provision strategy for local communities.

This quick overlook might suggest that pre-modern Alpine communities were isolated entities relying on adaptive farming strategies for their subsistence. This cannot be further from the truth. Members of the Alpine communities were actively engaged in various commercial enterprises, and small-scale workshops were commonplace in Alpine villages until the recent industrialization. Mobility has also been an important cultural trait of these communities, and seasonal emigration toward the plain was a vital risk mitigation strategy. Mining and metalworking have also been relevant productive activities for specific areas within the Alps, until very recently. All this shows that mountain communities are not isolated entities; they are instead nodes of complex regional and international networks, associated with craft production and trading, which significantly contributed to their socioeconomic development.

Pre-modern Alpine communities had a recognizable and unique character, which is the product of adaptation to the environment and nonlinear socioeconomic developments. This character is not only an essential component of current Alpine identity but corresponds to some of the most critical intangible heritage assets of Alpine

communities. The traditional practices mentioned above are currently promoted to foster tourism and sustainable landscape management in many sectors of the region. Investments and subsidies enable the surviving or revival of some of these traditions, hindered by globalization and depopulation. Within this unique framework, the archaeology of the Alps focuses on the identification of the historical or prehistoric roots of Alpine traditional practices and knowledge (Della Casa 2009). When did traditional farming start? When were the uplands first occupied by human groups? What is the history of Alpine mining? What is the evolution of Alpine mobility? Archaeology tackles all these questions and tries to provide chronological depth and solid temporal setting to the often misused concepts of "Alpine tradition" and "Alpine culture." Archaeology in the Alpine region is not only aimed at documenting the past but identifies continuities and discontinuities between the past and the present. This provides important information for development planning in the Alps: from sustainable tourism to rural development and from environmental protection to social cohesion.

Historical Background

Prehistoric studies in the Alpine regions date back to the very beginning of modern archaeology. The investigation of Neolithic lake-dwellings in Switzerland during the mid-nineteenth century can be reasonably considered a milestone in the early modern archaeology of continental Europe (Menotti 2001). The remarkable preservation of perishable materials in these lacustrine contexts contributed to shedding new light on prehistoric economy in Central and Southern Europe (Fig. 2). These earlier excavations, in turn, stimulated further archaeological investigations in the region, providing a better understanding of the prehistoric and early historic development of Alpine societies.

Archaeology of the Alps, Fig. 2 Bronze Age lake-dwellings in the Lake Ledro (Trentino, Italy). (Courtesy of Alessandro Fedrigotti)

One of the main site types investigated by archaeologists since the early twentieth century was the fortified strongholds. Often located in inaccessible positions, overlooking valleys or passes, they represent a key feature in the historic landscapes of the Alps. From prehistoric hillforts to medieval castles, these sites cover a long time span, and often the most recent ones reoccupy locations already fortified in earlier phases (Dal Ri et al. 2010). Representative examples of this site type are *Friaga/Bartholomäberg* (940 m asl) in Montafon (Austria), occupied in the Early to the Middle Bronze Age and again during the late Iron Age (Krause et al. 2004), and *Monte Barro* (650 m asl) near Lake Como (Italy), established in the Early Middle Ages (Brogiolo and Castelletti 1991). The interest of archaeologists for these sites is generally related to their architecture and connection with elites but also to their role as territorial markers and mobility/trading control points. It is worth pointing out, though, that the archaeology of hillforts and castles is not limited to the Alps, but characterizes every mountain region in Europe.

Caves and rock-shelters have also attracted the interest of Alpine archaeologists for decades. The main attribute of these contexts is the protracted occupation, often starting in early prehistory and continuing up to historical periods. Used as domestic, stabling, productive, ritual, funerary spaces, or a combination of these, caves and rock-shelters had a central role in the archaeology of the Alps. Some of these sites have provided crucial evidence to understand the long-term transformation of Alpine societies, economies, and cultures. One of the most interesting examples is *Riparo Gaban*, in the Trentino region (Italy). Occupied between the Mesolithic and the Medieval period (with various gaps), and investigated since the 1960s, it provided the first evidence of the eastern-Alpine Early Neolithic culture, today known as *Gaban facies* (Pedrotti 2002). Again, the use of rock-shelters and caves in different chronologies is not distinctive of the Alps, but is quite common in various mountainous contexts in Europe and beyond.

The archaeology of the Alps has remained confined to the valley bottoms and the mid-altitudes until quite recently. In the 1970s some pioneers have started investigating the recolonization of the subalpine and alpine zones of mountain ecosystems (1800–2500 m asl) at the end of the last Ice Age. Archaeological evidence of Late-Paleolithic and Mesolithic hunter-gatherers at high altitude was found in the Southern Alps and stimulated the emergence of related projects in other sectors of the region (Bagolini et al. 1994). But the real turning point in the archaeological exploration of the Alpine uplands is the discovery of the Iceman (aka Ötzi or Similaun man), a 5000-year-old mummy found at the Tisenjoch glacier (3213 m asl) in September 1991 (Egg and Spindler 2009). The information provided by this mummy (and by the equipment associated to it) revolutionized our understanding of the Alpine Neolithic and led to an increasing archaeological interest for the high mountains, previously considered marginal (Fig. 3).

Many other archaeological contexts have been investigated in the Alps during the last 170 years, besides the ones mentioned above. The increasing amount of data provided by archaeologists, complemented by archive sources for the most recent periods, shows that Alpine traditions have developed over time and are the product of complex processes. Recent collaborations between archaeologists and paleoecologist (who used to work in relative isolation until 20 years ago) have unravelled the long-term effects of human activities on mountain environments. This new knowledge contributes to strengthen the importance of Alpine traditions for the present and the future of Alpine societies, landscapes, and ecosystems.

Key Issues/Current Debates

As pointed out above, the interest of archaeologists for the Alps is multifaceted. And within this varied and dynamic framework, there are some research strands that have become particularly popular among Alpine archaeologists in the last decade. Novel methodological approaches, recent advances in archaeological science, and new research questions had an important role in the

Archaeology of the Alps, Fig. 3 Reconstruction of Ötzi the Iceman, by Kennis © Museo Archeologico dell'Alto Adige/foto-dpi.com

rising or strengthening of these strands. The outcomes of this new research fill some of the knowledge gaps related to human-environment interaction, socioeconomic evolution, and cultural change in the Alpine region (and beyond).

Pastoralism and Upland Occupation

Since the discovery of the Iceman (see above), the exploration of the uplands has progressively become one of the most intriguing branches of archaeological research in the Alps. The majority of the projects developed during the 1990s and the 2000s are diachronic and focus primarily on the analysis of pastoral occupation of mountain pasturelands: its origin, its development over time, and its role in shaping upland landscapes. One of the earliest research programs that addressed specifically these issues in a high mountain context is Kevin Walsh's and Florence Mocci's project in the Parc National des Ecrins (Southern French Alps) (Walsh et al. 2014). Extensive survey campaigns, archaeological excavations, and paleoecological analysis have revealed the complex history of human-environment interaction in this sector of the Western Alps, characterized by phases of "waxing and waning" associated with different drivers: from climatic fluctuations to socioeconomic upheavals (Fig. 4). During the last decade, new archaeological projects started in different parts of the Alps (like Silvretta Historica in Switzerland or ANISA in Austria), incrementing the amount of data available, as well as their geographical uniformity. These new data have been complemented by new analysis of the pastoral use of caves and rock-shelters during the Neolithic, often indicated by burnt dung layers called *fumiers* (Angelucci et al. 2009). These new projects have significantly improved our understanding of the evolution of pastoral practices, including the early phases of development of mobile pastoralism (Della Casa 2009; Walsh et al. 2014), the late prehistoric origin of summer dairy or *Alpwirtschaft* (Carrer et al. 2016), and the evolution of long-distance transhumance during the Roman period (Segard 2009). New archaeological data are challenging our perception of pastoral mobility and the origin of seasonal farming practices in the Alps.

The Exploitation of Mountain Resources

Many areas of the region provide rare and/or useful mineral resources, exploited since

Archaeology of the Alps, Fig. 4 Archaeological structures associated with pastoral activities in the Faravel Plateau (Parc des Ecrins, France). (Photo: Francesco Carrer)

prehistoric periods. Until the end of the Bronze Age, prehistoric communities largely relied on stone tools, and the raw material used to produce these tools (flint, chert, or rock crystal) was largely available in mountain areas. Human occupation of specific sectors of the Alpine arc was therefore motivated by the exploitation of lithic resources and not simply by subsistence needs. An interesting example of this is the Mesolithic rock crystal quarry identified at 2880 m asl in the Fuorcla da Strem (Grisons, Switzerland) (Reitmaier et al. 2016). The remote location of this procurement area provides an indirect evidence of the territorial knowledge and understanding of resource distribution of Alpine groups since prehistoric times. Green rocks were also exploited since the Neolithic for producing axe blades and ornaments (Della Casa 2005), many of which were probably attributed a symbolic value. Their large diffusion, beyond the extraction areas, suggests routes of exchange that confirm the mobility of Alpine population since these early prehistoric phases (see below).

Besides lithic resources, metal ore has been the primary raw material extracted in the Alps until modern times. Dedicated research projects have enabled the identification of numerous mines in different sectors of the Alps (Stöllner and Oeggl 2015), exploited in prehistoric or historical periods (Fig. 5). Smelting and roasting sites associated with these mines have also been identified, thus enabling a better understanding of metalworking *chaine operatoire*. Furthermore, new chemical methods are increasingly employed to track the origin of metal objects and to understand their distribution. This has contributed to the identification, for example, of an interesting E/W division between metallurgy traditions in the Alpine region, which defines most of the prehistoric periods and

Archaeology of the Alps, Fig. 5 Glance (galena) mine in the Col Piombin (Dolomites, Italy), exploited until the 1750s. (Photo: Fabio Cavulli)

might mirror underlying sociocultural factors that we still know very little about (Perucchetti et al. 2015).

Another important mineral was exploited in the Alps: salt. The earliest exploitation of the salt mines of Hallstatt (Austria) starts in the Bronze Age, and it leads to the development of a rich and socially complex mountain community, at the center of large-scale networks of exchange. This important development is mirrored by the necropolis of Hallstatt, one of the richest late prehistoric cemeteries of Europe, which gave the name to the central European EIA culture. Recent research in the mines yielded an incredible amount of archaeological material culture, including numerous artifacts made of organic material (leather, wood, etc.) perfectly preserved. These remarkable finds have shed new light on the organization of mining in prehistoric times, on the lifeways of miners, and in general on the character of a prehistoric community in the Eastern Alps (Reschreiter and Kowarik 2019).

Transalpine Connections

The difficult accessibility of the mountains has contributed to picturing mountainous regions as barriers and as natural border zones. Indeed, they have been perceived like that in many historical periods. Roman literature provides a description of the Alpine region as remote and impervious, and large defensive infrastructures were built in the Eastern Alps during the fourth and fifth century AD, to protect the Po plain and the Italian peninsula from the raids of "barbarian" armed groups. The "Alps as frontier" narrative recurred also during the Great War (World War I), as many Alpine summits and passes were battlefields for the armies of the Austrian Empire and the

Kingdom of Italy: defending the Alps was equivalent to defending the motherland.

However, this has not always been the case. In different historical periods, the Alps were a diaphragm, a connection between the great plains of central Europe and the Mediterranean coasts. The Alps have developed distinctive cultures and facilitated the movement of people, goods, and innovative ideas. Archaeology has played a prominent role in challenging the stereotypical perception of the Alps. Since the Paleolithic, tools produced with flint collected in the Southern Alps are regularly found beyond the Alpine watershed. This shows the large mobility of prehistoric hunter-gatherers, within and across the Alpine region (Visentin et al. 2016). As mentioned before, the large diffusion of stone axe blades and ornaments suggests the existence of prehistoric routes of exchange that crossed the mountains and connected communities within and beyond the Alpine region (Della Casa 2005). It is difficult to assess whether the movements of these artifacts imply movements of people or more sophisticated exchange networks; nevertheless, it can be argued that the roughness of the Alpine landscapes was not an impediment. Recent remarkable archaeological discoveries in ice patches and retreating glaciers (Fig. 6) confirm that high mountain passes were crossed in different prehistoric and historical periods, providing a glimpse of the variability of mobility strategies in mountain environments (Hafner 2012).

All these data suggest that the Alps, including their uplands, have been an interface of critical importance for the development of connections between Southern and Central Europe. By constraining mobility through privileged crossing points, the Alps have selectively linked the north and the south of the region more closely than the east and the west, thus influencing their socioeconomic and cultural development. Archaeology is highlighting the long-lasting role of the Alps as

Archaeology of the Alps, Fig. 6 Archaeologists recording and collecting finds in the area uncovered by a retreating glacier (South Tyrol, Italy). (Courtesy of Arc-Team (http://www.arc-team.com/))

source, corridor, and destination of important routes, which was assumed but largely unknown only few decades ago.

The Symbolic and Ritual Value of the Mountains

Many mountainous areas are considered sacred spaces by different cultures around the world, and the Alps are no different from this point of view. The symbolic or ritual significance of summits and caves is extensively investigated in the ethnographic and historical literature. Sanctuaries are very typical landscape features in the Alps, as much as in many other mountain regions. Some of these sacred places had a long and complex historical development and survived till nowadays. For example, Early Christian hermitages often developed into churches or abbeys, influencing landscape perception in the area for centuries or millennia.

The most significant Alpine sanctuaries are well-known from literature. For periods lacking written sources, archaeological evidence provides a crucial contribution. Late prehistoric examples of ritual sites are the so-called *Brandopferplätze*. This category, in fact, includes different types of contexts, particularly common in the Northern Alps during the Bronze and the Iron Age. Their locational pattern is not uniform, as they have been found near the valley bottoms or in remote upland areas. They also show diverse internal organizations: some are complex and well-structured sites with different sectors used for different activities, and others are much simpler and with more ephemeral architectures. However, they are all characterized by large bonfires used for ritual offering. Offerings are primarily animal parts, but they also include domestic and wild plants, pottery, prestige goods like metal objects (comprising coins in later periods), and even amber beads (Steiner 2010). The chronology of these contexts is quite varied, and some are occupied until the end of the Roman period. Scientific methods and the expansion of research are providing new exciting information and shedding new light on this interesting phenomenon. Recent research in South Tyrol, for instance, suggests that *Brandopferplätze* were a key feature of high-altitude landscapes during the Bronze Age (Putzer et al. 2016).

Rock art represents interesting evidence associated to the symbolic and ritual role of mountain landscapes. Figurative and schematic representations engraved in boulders and rock outcrops are widespread all over the Alpine arc and cover a broad chronological range, from prehistory to the modern period. It is worth mentioning two context among the most relevant in the Alps and in Europe: the *Vallée des Merveilles* ("the valley of marvels") and *Vallée de Fontanalba* of Mount Bego in France (de Lumley and Echassoux 2011) and the *Valcamonica*, UNESCO Heritage Site of Italy since 1979 (Anati 2015). The rock art of Monte Bego is primarily located at high altitude and is often associated to the pastoral occupation of mountain pastures, as well as to mobility routes through the uplands. In Valcamonica, rock engravings are not only clustered in ritual places (Fig. 7),

Archaeology of the Alps, Fig. 7 Cemmo's boulder (Valcamonica, Italy) displaying numerous prehistoric engravings. (Courtesy of Ausilio Priuli)

but they are also scattered in many other locations: they were associated not only with rituality but also with everyday activities. The oldest reliably dated rock engravings in these two areas belong to late Neolithic, but an earlier date has been suggested for some of them. Digital technologies and new interpretative models are contributing to changing our perspective toward Alpine rock art. Much more attention is paid today on the location of the engravings, on the geology of the support, on the tools used to produce them, and on their preservation. Many iconographic motives have been reinterpreted in the last years, and the growth of mountain research has provided new parallels from the Alps and other mountain regions. The study of rock art today is an integral part of landscape archaeology projects in the Alps and provides a much more detailed understanding of human interaction with their territory.

International Perspectives

For long time, archaeological research in the Alps has been connected to national archaeological traditions. Research themes and strategies were different in France, Italy, Austria, Switzerland, Germany, and Slovenia. It has become clear quite early on that Alpine cultures crossed current national borders and that archaeologists had to be aware of what their colleagues were finding in neighboring countries. Today the archaeology of the Alps overcomes the different national traditions, and data are regularly shared among the different research groups. A potential limitation to the development of a real collaborative research environment is the linguistic difference within the Alps. Many publications and reports of crucial importance are still written in Italian, German, or French, and this makes it more difficult for scholars to keep up to date. Increasing number of journal articles and volumes in English and the development of Web-GIS projects including the Alps (like ArkeoGIS.org or the Archaeological Information System in apsat.mpasol.it) are improving this situation and contributing to a real integration of Alpine archaeological research.

Future Directions

The archaeology of the Alps is changing fast, incorporating new methodological approaches, and reshaping its goals and theoretical framework. Four key themes that have been emerging in the last decade deserve further attention. It is worth pointing out that these are not the only themes that archaeology of the Alps is expected to focus on in the near future. These are just the themes that, based on my personal research experience and expertise, seem more challenging and at the same time more promising.

Spread of Farming in the Alps

Research on the spread of plant and animal farming in Europe during the Neolithic has increased in the last years, thanks to new scientific techniques and new interpretative approaches that changed the way we look at this phenomenon. However, the Alpine region is still underinvestigated from this point of view. Agriculture and pastoralism penetrated in the Alpine valleys much later than in the surrounding plains (Pedrotti 2002), but the mechanisms of diffusion and assimilation of these strategies are still largely speculative. Pioneering research on this topic is taking place in other mountain regions (Pyrenees, Balkans), and it is likely to be one of the most interesting research questions in the Alps during the next decade.

The Impact of Bioarchaeology

The rapid development of bioarchaeology is opening new perspectives for archaeology, by answering long-standing questions and replacing them with new ones. The archaeology of the Alps is already strongly influenced by scientific methods (e.g., the innumerable analysis undertaken on the Iceman mummy; Egg and Spindler 2009), and this influence will grow exponentially in the next decade. Isotope analysis will be increasingly used to understand cuisine and mobility of past mountain communities and to explore climatic fluctuations at local scale. Proteomics will enable a reliable identification of the animal and plant species used to produce artifacts.

The analysis of dental calculus will provide detailed information about individual diet. Ancient DNA will disclose migrations and lineage relationships between Alpine groups and will track the origin of domesticated Alpine fauna. As these techniques develop and become more established, their use increases in the Alps. As more Alpine projects include bioarchaeology, the inferences produced become more generalizable.

Glacial Archaeology

It is widely known that climate change will have dramatic consequences for mountain environments, as previously pointed out. Among these consequences there is also the loss of important cultural heritage. Glacier retreat is exposing traces of human presence at high altitude (Hafner 2012), and most of these are made of organic material (leather, wood, etc.) and might be lost if not recovered in time. This new awareness is stimulating a series of "rescue archaeology" projects in glaciers and ice patches, as well as the production of heritage risk maps for the high mountains. The protection and promotion of cultural heritage in the Alps are reaching the remote glacial landscapes at 3000 m of elevation, and global warming will increase the urgency and the extent of archaeological interventions in the nival zone of montane ecosystems.

Land Management and Sustainability

Promoting sustainable management of the landscape is one of the key priorities of policymakers engaged with the Alpine region. Landscape and environmental archaeology projects in the Alps will contribute to inform development and planning, providing a solid understanding of long-term socio-ecological dynamics. This ecological and societal role of archaeology is increasingly popular in some of the most endangered ecosystems in the world (e.g., the Amazon, the Sahara desert, etc.), but has long been overlooked in the European mountains. Today there is growing awareness that understanding the history of mountain landscapes is crucial to predict and manage their future. In order to influence decision-making, the archaeology of the Alps needs to expand its collaborations with other scientific fields (ecology, ethnography, economy) and adapt its research questions to the new challenges of our times.

Archaeology of the Jesuit Missions of Ethiopia

Víctor M. Fernández
Dpto. Prehistoria, Historia Antigua y Arqueología, Universidad Complutense de Madrid, Madrid, Spain

Introduction

Catholic Jesuit missionaries, from Portugal, Spain, and Italy, were active in the Christian kingdom of Ethiopia, known then in Europe as the kingdom of Prester John, since 1557 until their expulsion in 1632–1633. They erected their first churches and buildings early during the mission, using local techniques with dry stone, stone and mud, and perishable materials. After 1622, when king Susenyos was converted to the Catholic faith, they began a vast program of architectonic constructions, which reached its apex after the introduction, in 1624, of the lime mortar technique. The many structures made thereafter, with

stone and mortar, though most of them heavily ruined, have remained until today.

According to the missionary record, the Jesuits established 19 residences in Ethiopia, although only 14 of them were inhabited for a consistent period of time. In at least ten residences, with the help of foreign and local masons and within a short span of time (1624–1632), they erected or started to build sophisticated structures that included stone and mortar churches, residences, schools, water conductions, large cisterns, bulwarks, and towers.

State of Knowledge

From 2006 to 2014, a Spanish archaeological team from Complutense University of Madrid, with the assistance of members of other institutions, carried out a program of research on the missions whose location is known, all of them around the lake Tana in central historical Ethiopia, as well as on the mission of Feremona in the northern region of Tigray. Special attention and extensive excavations were undertaken in the sites of Azezo-Gennete Iyesus near Gonder and Gorgora Nova on the northern shore of lake Tana, and, to a lesser extent, on the mission of Serka to the south of lake Tana. Archaeological surface survey was made on all the known sites, including GPR survey in Azezo, high-definition topographic survey was made on the best preserved sites (with the exception of Mertule Maryam, for technical impediments), and 3D Scanning was applied to the four main sites north of lake Tana (Azezo, Gorgora Nova, Denqez and Debsan). The complete results of the project were published in Fernández et al. (2017) and the 3D videos are available in Youtube. Previous archaeological work on the sites was published by Francis Anfray (1980–1981, 1988) and Tsega Michael (1998), and recent general studies on the Jesuit period in Ethiopia are Pennec (2003), Ramos and Boavida (2004), Cohen (2009), and Martínez d'Alòs-Moner (2015). The greater part of the reports and books written by the Jesuits during the time of the mission and immediately thereafter were compiled by Camilo Beccari in RASO (1903–1917).

The history of the mission can be divided into two clearly distinguished periods. The first period extended some 40 years, from the arrival of the first missionaries at the hand of the Spanish bishop Andrés de Oviedo until the end of the sixteenth century. This phase was characterized by stagnation and estrangement from the Ethiopian court. The second and most successful missionary phase began in 1603 and continued up to 1632. During this period, the missionaries befriended influential members of the Ethiopian court, first and foremost the Christian Ethiopian ruler, *negus* Susenyos, and his half-brother Seʿela Krestos. Under the leadership of men like the Spaniard Pedro Páez, the Portuguese António Fernandes and Manoel de Almeida, and later the Portuguese Afonso Mendes, appointed Patriarch of Ethiopia in 1625, the missionaries could intensify its activities. In the early 1620s, Susenyos declared Catholicism the state religion but the success of the mission was, however, short-lived for in 1632, amidst a civil war and a dynastic succession crisis, the missionaries were expulsed from the country.

The areas of activity and settlement of the missionaries were, broadly speaking, those of the royal monarchy and its court. Fourteen residences were located in the area surrounding Lake Ṭana and near the royal and provincial capitals, particularly to the North, East, and South of the lake, in the regions of Dembiya, Begemder, and Gojjam, respectively. Since the missionaries depended on the protection and patronage of the monarch and powerful lords, it is also in those areas where they erected their most ambitious constructions.

The exact location of ten Jesuit residences in the area surrounding Lake Ṭana is for the most part known: Azezo (also known as Gennete Iyesus), Gorgora "Nova," and Gorgora "Velha" (the location of the latter is not yet sure) in Dembiya; Debsan (Enfraz) and Denqez in Begemder; Serka, Hadasha, Qwellela, Merṭule Maryam (Ennebesse), and Lejje Negus in Gojjam. The location of the first and most enduring mission, Feremona in Tigray near the Eritrean border, is also known. A further eight sites, the "lost missions," have not been located yet (Anfray 1980–1981, 1988; Fernández et al. 2017: 35–438) (Fig. 1).

Archaeology of the Jesuit Missions of Ethiopia, Fig. 1 The Jesuit missionary network in Ethiopia and the royal courts (*ketema*). The spelling of the site names in the map follow the guidelines of the Encyclopaedia Aethiopica (Harrassowitz, 2003–2014)

The intention of missionary architecture in Ethiopia was multiple. Firstly, the missionaries were looking for structures suitable to the development of their proselytizing and intellectual activities. Secondly, they were eager to impress their patrons and the local people with sophisticated and technically improved constructions. Last but not least, the Ethiopian patrons, in particular Susenyos and Seʿela Krestos, used the building skills of the Jesuits and the masons who came with them from India to produce an architecture symbolizing their power and ideals for renewal and cultured life-style.

One of the most important missions was located in Azezo, 10 km south of Gonder, receiving the name of Gennete Iyesus, the Garden of Jesus. In 1624 the Jesuits built a small residence or palace for King Susenyos using stone and mortar, with a round tower that probably served as a model for the later Gonderine towers (Fig. 2). In one of the rooms of the palace, there was a water system that was probably a latrine or bathroom and besides the entrance stairs three individual latrines were built that drained through an underground channel to a nearby stream. Shortly after, the missionaries reformed with mortar a rectangular, single-nave church that Pedro Páez had erected with dry stone before the introduction of the mortar. The church was surrounded with a rectangular fortification endowed with round towers in the corners and in the middle of the long sections. Around the same time, they built for the king a large pool of water with a rectangular pavilion in the middle, following the pattern of the royal Indian pools and pavilions (*talao*) of the Mughal culture (Fernández et al. 2017: 59–189).

Equally important was the mission of Gorgora, on the north coast of Lake Tana. Pedro Páez created there a first settlement of buildings still without mortar (the "old" Gorgora, Gorgora Velha), whose location can, for the time being, only be guessed. Nearby, on a small peninsula on Lake Tana, Páez erected a two-story palace for the king, which Susenyos used between 1614 and 1618. Later, on the same site of the palace, the Jesuits began to build a large church around 1626, with a single nave and a recessed apse, endowed with an extraordinary decoration in carved stone both in its walls with circular, blind windows as in the vault (Fig. 3). Attached to the church was

Archaeology of the Jesuit Missions of Ethiopia, Fig. 2 Excavations at the royal palace of Azezo-Gennete Iyesus with the standing ruins of the round tower in the middle

Archaeology of the Jesuit Missions of Ethiopia, Fig. 3 The remains of the apse vault in the Gorgora Nova church. (Photo 2006)

Archaeology of the Jesuit Missions of Ethiopia, Fig. 4 The western tower and cells of the Gorgora Nova residence

a large courtyard-cloister and a residence for priests and students, with nine cells and two square towers at the corners, of two stories each (Fig. 4); the ruins are known locally as "Susenyos palace." In the eastern tower, there was a bathroom with a stone floor that drained the water into a deep well from which an underground conduit flowed into the lake. At present, part of the apse vault and the walls of the residence are conserved (Fernández et al. 2017: 189–303).

In 1618, King Susenyos moved his court to Denqez, at a point of greater height and better

sanitary conditions than the coast of Lake Tana, where malaria was endemic. There the missionaries, with the help of Indian, Egyptian, and local technicians, built a large palace of several floors for him, whose walls are still preserved today, with floral drawings of various colours over the walls' internal plaster. At a short distance, the Jesuits built a church, destined to be the Catholic cathedral of the country, shaped as a Latin cross plan with a transversal transept, from which the walls and arches are also preserved. Farther south, in Debsan on the top of a hill overlooking Lake Tana, the missionaries built a long rectangular building that served as Patriarch Mendes' residence until the expulsion (Fernández et al. 2017: 303–354).

South of Lake Tana, the most important missionary residence was that of Merṭule Maryam, where before there had been an orthodox monastery built around one century before by Queen Eleni. Although it was not finished, the high walls of the head of a church with three naves are still well preserved including very rich sculpted decorations (Fig. 5). Also in the region of Gojjam, in Serka, a mission was built next to the residence of the *Ras* (local governor) Seʿela Krestos, with a church of a single nave that still retains the walls and a beautiful arch of reddish stone. Of the other three missions known in Gojjam, Abba Gish Fasil (probably the mission of Lejje Negus), Qwellela, and Hadasha, only the first preserves some remains of a building, of unknown function, and a wall with defensive embrasures and a water deposit, on top of a high hill. In the mission of Qwellela there are only the scarce remains of a high wall, and in Hadasha we have only registered a defensive earth embankment, cited in the Jesuit texts (Fernández et al. 2017: 411–434).

In the northern region of Tigray, of the residence of Feremona, the first built and the last to be abandoned, no remains of any building have been preserved (with the exception of a few square blocks of the church that had begun to be built). The fortification erected around the mission hill, with flat stones bound only with mud because lime for mortar was difficult to find in the area,

Archaeology of the Jesuit Missions of Ethiopia, Fig. 5 Decorated blocks from the central nave arch in the Mertule Maryam church. See in the middle the graffito with his name written in 1842 by the English traveller, Charles T. Beke

is largely well preserved, including two of its round bastions (Fernández et al. 2017: 42–59).

When the Jesuits were expulsed from the kingdom in 1632, some of the structures were abandoned and some were reutilized for other purposes. Most of the buildings were ruined through the centuries but a few, like Gorgora Nova, Denqez, Debsan, and Serka, managed to preserve part of their structures remarkably intact.

A curious fact recorded by the archaeological project is that the Orthodox changed the significance of the Catholic churches to convert them to the traditional faith of the country. Thus, in several buildings (Debsan, Serka), new walls were built to divide the Jesuit open space into a new triple division as is usual in the eastern churches, or a new Orthodox church was built on top (Azezo) or in the middle of the Catholic buildings (Gorgora Nova, Merṭule Maryam). The

latter three buildings were not made immediately after the missionaries' expulsion as they were constructed with stone and mud, and the mortar technique seems to have been lost at the end of the Gonderine period around the mid-eighteenth century. In the two constructions that had underground conduits for bathrooms or latrines (Gorgora Nova, Azezo), these were destroyed or the wells were intentionally blocked, as if the new technologies were identified with the Roman heresy.

Current Debates

The traditional historiography on the Jesuit period in Ethiopia is divided into two main currents, favorable and critical. As expected, Jesuit historians and Catholics in general pay attention to the modernizing work that the missionaries carried out, introducing European ideas and techniques in a still very backward region, in addition to conducting and publishing very advanced studies for their time on that unknown part of Africa, long before the first European explorers arrived during the nineteenth century (e.g., Caraman 1985). In contrast, most Anglophone authors, together with contemporary Ethiopian historians, have presented almost to this day a rather negative view based on the division and wars that the intruders provoked in the country (e.g., Pankhurst 1998; Merid 1998), which unfortunately seems to have influenced the general neglected state of the Jesuit ruins.

There is general agreement about the Jesuit influence in the reinforcement of the Abyssinian monarchy. Before the missions, the kings changed residence frequently (it was a peripatetic monarchy) erecting large camps with perishable materials, but as soon as the missionaries left the country, the new king Fasiledes chose Gonder as a fixed capital. He also built an impressive four-story palace of square plan with circular towers in its corners, the Fasil Ghimb (one of the main visual symbols of the country and a tourist icon). These structures undoubtedly sought to reinforce the ruler's image of authority before its subjects and above all in the face of the rebellious regional nobility. The origin and models of that architecture, which was later completed by his successors while Gonder remained the capital until the mid-eighteenth century, has been much discussed, with most "post-colonial" local and Anglophone historians favoring an oriental origin (India, Ottoman Empire), rather than a European influence. However, the great resemblance between these buildings and the palace and fortifications erected very close by the missionaries (in Azezo, only a few kilometres from Gonder) makes it difficult not to think that their inspiration (together with the permanence in the country of the Indian technicians who had accompanied the missionaries from Goa and Diu) was crucial in the formation of Gonderine architecture.

Archaeology of the Majimaji War

Nancy A. Rushohora
Studies in Historical Trauma and Transformation, Stellenbosch University, Western Cape, South Africa

Introduction

The Majimaji war, which occurred in 1905–1907, was a resistance against German colonial domination in southern Tanzania. The war spread to over 260,000 km^2 of southern Tanzania covering seven regions, namely, Lindi, Mtwara, Ruvuma, Pwani, Njombe, Morogoro, and Dar es Salaam. More than 20 ethnic groups participated including the Mwera, Makonde, Makua, Yao, Ngindo, Matumbi, Bena, Zaramo, Ndengereko, Matengo Ndendeule, and Ngoni. Some of the prominent Majimaji warriors from these ethnic groups include Songea Mbano of the Ngoni, Selemani Mamba of the Mwera, Abdalah Mchimai of the Ngindo, Mpangile of the Bena, Lindimyo of the Matumbi, and Kibasila of the Zaramo. The numbers of people who participated in the war, those who died and the survivors, are uncertain. This is because there was no deliberate enumeration of the whole population in Tanzania before 1948 (Thomas 1968); available before this date are estimates rather than census. The German financial year report of 1906/1907 presented in 1908/1909 had estimated the figure of Majimaji causalities at 75,000 (Gwassa 2005). The Tanzanian historian Gilbert Gwassa estimated in 1973 that between 100,000 and 120,000 people died of the war. Altogether, depopulation is one of the legendry aftermaths of the Majimaji war.

Definition

The term Majimaji emerged out of the instructions of the ritualistic war leader named Kinjekitile Ngwale who instructed the words *Maji Maji* to be uttered whenever the Germans shot Tanzanian soldiers. Kinjekitile instructed that, when fighting, the soldiers should all look forward and pronounce the words M*aji! Maji!* It is from these words that Majimaji acquired its name. *Maji* is a Swahili term which means water. Kinjekitile prepared *Maji* – which was a liquid concoction used as the war medicine. *Maji* medicine is intended to immunize, cure, or protect the Majimaji fighters, their families, and properties during the war. It was believed that the use of *Maji* would turn the German bullets into water and bullets would fall off like water on an oiled body (Gwassa 1973). However, the medicine was ineffective and the Tanzanians were defeated. The term Majimaji was publicized by the colonial era publications (Sunseri 1999). This partly accounts for the English orthography that has been used in writing of term either as two separate entities, "Maji Maji" or with an intervening hyphen "Maji-Maji." The use of the term as two different entities Maji Maji has also been attributed to the retaining of the original cry that the Majimaji fighters uttered

during the war. Nevertheless, the original cry that Majimaji fighters uttered was according to the ethnic groups. For instance, the Matumbi used the words Mase Mase, while the Ngoni used Manji Manji, all translated to mean water. Scholars such as Sunseri (1999) have used the term Majimaji inconsistently either following the Swahili grammar or English but without explaining why they incline into that orthography. Majimaji as a term retains Swahili identity whereby Swahili grammatical conventions specify that compounds should be written as one word, thus Majimaji.

In Africa, the archaeology of resistance is nearly absent. Although much excellent work has been done on symbolic resistance, hybridity, and cultural negotiation by postcolonial archaeologists such as Hall (1993), issues of overt violence have seldom been addressed. The little available literature has shortcomings either evincing western bias or delving into military details, forgetting the larger historical and social picture (Gonzalez-Ruibal et al. 2011). The term archaeology of resistance on the other hand can be a misnomer as African resistances range from slavery to colonialism and post colonialism all existing in multiple forms of both passive and active resistance. Slaves' resistance, for instance, includes behaviors such as sabotage, feigned sickness, intentional tool damage, strikes, slowdowns, poisoning, and arson (Weik 1997:84), whereas resistance to colonialism involved armed struggle and active militarism. In the broadest sense, approach to the archaeology of African resistance has been conducted as historical archaeologies of ancient colonialism and imperialism or historical archaeology of modernity and expansion (Gonzalez-Ruibal et al. 2011). Nevertheless, historical archaeology in Africa is informed by diverse sources and multiple histories; as a result there is no single but rather multiple historical archaeologies on the continent (Pikirayi 2006). Archaeology of African resistance is thus a discipline of its own right. By looking at guerrilla bases, colonial military camps, and burnt-down indigenous villages, the archaeology of African resistance can offer a counterpoint to visions of cultural contact and colonialism from Roman times to nineteenth-century colonialism. The archaeology of resistance can also employ social accounts whereby different actors are brought into play, especially those that have been doubly ignored, women, children, and the elderly. Thus, approach to the archaeology of resistance in Africa is an essential tool to elucidate the role of different agencies, participants of the resistance, the landscape of resistance, and the nature of resistance as these were not uniform throughout the continent. The archaeology of resistance can also yield memories and the use of the same by the contemporary African communities.

Historical Background

The initial battlefield of the Majimaji war was Nandete in Lindi region and among the Matumbi people. To initiate the war, two patriotic warriors, namely, Ngulumbalyo Mandai and Lindimyo Machela, after they have used the war medicine – *Maji* – uprooted cotton plants from the German colonial plantation located at Sikwaku hill, 10°54′0"S/38°47′60″E. This ignited the war in Umatumbi in mid-July 1905. From its first battle, the Majimaji war spread rapidly to other parts of southern Tanzania. For example, the war broke out in Liwale on 13 August 1905 (Libaba 1968), on 16 August 1905 among the Pogoro (Iliffe 1979a), by the end of August among the Zaramo (Sunseri 1999), and 3 September among the Ngoni. This happened 3 years after the establishment of the cotton plantation. The cotton plantation economy was not beneficial to the southern Tanzanian people because of the harsh and inefficient way in which the scheme was handled. Hardship and suffering were caused, and the scheme did not benefit the local people (Giblin and Monson 2010). As mentioned above, the war was initiated by the Matumbi, but more than 20 ethnic groups joined the resistance with the interest to fight the Germans.

The Majimaji warriors were bounded together by rituals and traditions spearheaded by Kinjekitile Ngwale, a medicine man who lived at Ngarambi, west of Kipatimu. Kinjekitile declared that by sprinkling, bathing, or rubbing people with

medicinal water (*Maji*), he could provide them with immunity against the Germans bullets. Both the *Maji* medicine and the message of the war outbreak were spread by the Majimaji messengers. It is thus believed that *Maji* was an important organizational device (Gwassa 1973: 11). However, the acceptance and utilization of *Maji* created considerable ethnic confusion and variations, and receipt of the same varied widely. For instance, while *Maji* spread in some areas prior to the war, other battle sites received *Maji* long after the war had begun in their areas. Thus, the beginning of the Majimaji war differed in time from one battle site to the other. The Ngoni received *Maji* and the Majimaji at the same time, the Matumbi received *Maji* first and began the Majimaji, and the Yao received Majimaji before *Maji.*

The spread of the Majimaji war from one ethnic group to another forms a pattern in historical narratives. This is because the Majimaji situation stimulated different modes of reactions among southern Tanzanian ethnic groups. The majority of the ethnic groups in southern Tanzania joined the war, although sometimes they did so without support of their rulers. A number of headmen who were their rulers were forced to join the war only after a threat of being killed as enemies. Other ethnic groups such as most of the coastal peoples, the Matengo and the Yao, remained militarily passive. Individual African agents were also recruited as mercenaries for the Germany army. Therefore, ethnic groups and sometimes people of the same ethnic group reacted differently to the Majimaji war movement.

Key Issues

Archaeological survey, excavations, document analysis, and ethnographic enquiries that have been conducted in southern Tanzania have yielded a trail of sites, landscape, and memories attributed to different episodes of the Majimaji war. They include the cotton plantation source of the war, battle sites, battle landscape, refuge caves, execution trees, mass graves, numerous German administrative posts (*boma*) from which the war commands emanated from, and ritual sites as a spiritual panacea to the hardship of the war. These add on to memories, memorials, and memorialization activities that have been adopted by the contemporary communities to remember the havoc of the Majimaji war. As material past, the Majimaji war remains have been interpreted to elucidate the Majimaji peoples, warriors, landscape, and weapons (Rushohora 2015). The Majimaji people, for instance, are the people whose antecedents participated in the Majimaji war. These people are geographically living in the aforementioned seven regions of mainland Tanzania renowned in oral and written sources to have been involved in the warfare. In addition, material traces of the past, features, landscape, and memories attest to their being. The Mwera, Matumbi, and Ngindo in Lindi region, the Ngoni and Ndendeule in Ruvuma region, and the Makua of Mtwara region (just to mention a few) are the Majimaji peoples. The Majimaji warriors on the other hand were men of younger and middle age. The warriors were identified during the war with bottles of *Maji*; white, blue, or black *kaniki* cloth; and a headband threaded with stalks of millet or maize tied on their forehead (Gwassa 1973). Then, the Majimaji victims were both women and men. During the Majimaji war, women were used as spies and offered a constant supply of food to the warriors. For this reason, colonial troops detained both men and women as hostages in order to establish whether they were Majimaji supporters or loyalists. The same technique was used to force surrender by preventing supplies reaching the warrior bands (Schmidt 2010: 206).

The Majimaji war's paramount weapon was *Maji* (Becker 2004: 20). *Maji*, as a medicine, was a carrier of a multitude of social meanings. Prophet diviners of *Maji* played the role of military guidance although they were not combatants in the war itself (Monson 2010: 35). Military leaders used medicines as the war strategy to ensure or coerce loyalty and commitment among their soldiers (Monson 2010: 46). Rituals and medicine were perceived as instruments of invulnerability in time of war (Monson 2010: 36) and Maji as medicine of immortality (Gwassa 1973). Other weapons of the Majimaji war included

stones, spears, sticks, knives, shields, bows, and poisonous arrows. Although the southern Tanzania region and people were diverse, the weapons used for fighting throughout the Majimaji region were of the same nature (Monson 2010: 35). However, the Ngoni used cowhide shields, clubs, and stabbing spears in addition to other weapons (Becker 2004: 4), while some Africans throughout the region used guns (Makweta 1968: 2). The Germans' weapons were solely guns.

Another prominent legacy of the Majimaji war is memory. The Majimaji memories can be assigned to three levels of agents: the individual, the small group, and the collective. The individual Majimaji memories are those formed by remnants of families of the leaders of the war, the known warriors, and *Maji* (Majimaji medicine) agents. The small group's memories involve villages, districts, and the de facto regional scale. Collective memory involves the teachings of Majimaji as part of the national history project and creation of commemoration days, activities, and rituals. On individual memory, for example, some families of the Majimaji warriors forget or ignore the war memories, while others are keen to remember them. Ignoring the Majimaji warriors or at least disassociation with them mostly appear when the Majimaji warriors committed murder of German solders or their associates like the German missionaries and happened to be identified as the murderer. These Majimaji warriors are like Seleman Mamba and Abdallah Mchimaye. On the other hand, Majimaji warriors that made a pivotal contribution either in leading the battalion or prolonging the war until their arrest are memorialized by their individual families. Examples of such warriors include Songea Mbano Lwafu, the sub-chief and war general of the Ngoni. The family of this warrior performs rituals at his refuge cave and participates in the Songea commemoration events every year to keep his memories alive. The small group's memories include the celebration of individual warrior or warriors related to a particular village or region. Kinjekitile Ngwale memories, for example, are kept by the people of his village. One hamlet in the village is named after him, and until 1997, primary school graduations were held in ruins of his residential house and ritual site source of *Maji*. The collective memory of the Majimaji war in Tanzania as a country has seen the Majimaji war integrated in history syllabi from primary schools to the college level. The Majimaji heroes are celebrated on the heroes' day, and the war is regarded as a cornerstone of the countries' liberation against colonial domination.

International Perspectives

Different countries and communities choose different paths of recovery from colonial wars, trauma, and atrocities ranging from heritage therapy, human rights activism, juridical proceedings, apology, and truth revealing. In South Africa, for example, Lynn Meskell and Colette Scheermeyer point that production of objects, memorials, museums, heritage sites, and public spaces of commemoration has provided a therapeutic arena underpinning amnesty and the desire to move forward as a nation (Meskell and Scheermeyer 2008). In Rwanda and Uganda, John Giblin attempts to use international, national, and subnational post-conflict policies of healing heritage to conceptualize cultural process, cultural trauma, and symbolic healing, respectively. This led him to conclude that heritage is neither an essentially positive nor negative post-conflict remedy to select or avoid (Giblin 2014). Remedy especially after the Majimaji war is conceptualized as a procedure by which relief is obtained for individual or a community that suffered physical, mental, or emotional injury and economic loss. It is over a century since the Majimaji war occurred, and the contemporary communities desire for remedy. Remedy from the Majimaji war is very important given the fact that the trauma neither allowed appropriate mourning nor burial. The Majimaji war victims passed through different phases of a forceful total silence, nationalization, and community ownership. A forceful total silence was a safe option during the colonial period because the war was categorized as a revolt/rebellion; calling it a war was a punishable offense (Lawi 2009). Silence period was immediately after the war which saw the demarcation of southern Tanzania as a "rebel

area," (Jamaliddini 2006) and the hardest punishment that this region received was developmental backwater which has been difficult to recover up to date (Koponen 2010). Remedying strategy that was used during this period was migration from the Majimaji war zone to other parts of the country living the area with population denudation which took very long to recover (Gwassa 1973). The second phase was the nationalization and national commemoration period which commenced in the 1960s when the war was nationalized and identified as an independence movement attempt (Sunseri 1999; Ranger 1968). Tanzanians historical scholarship of the war began during this period hand in hand with entry into the history pedagogy from primary to college level emphasizing the Majimaji as a heroic independence movement. Even in the history of the Tanzanian army (Tanzania People's Defense Force – TPDF), the Majimaji war military techniques such as the guerilla wars and the use of shield and spears are mentioned as the indigenous forms of defense in Tanzania and origin of the military evolution in the country. The nationalization phase considered not the communities that were affected by the Majimaji war but the entire country as being built on the ashes of heroes and heroines of colonial resistance. Communities therefore required healing.

Reparation is one form of healing that the Majimaji war peoples demand from the Germans. The Majimaji commemoration events in Songea have always been the venue for the local voices about reparation. Demand for reparation does not mean that memory of trauma can be erased, but transformed in positive ways, and new narratives can make sense of past trauma. The Germans may have paid symbolic reparation through scholarships and aid to the government of Tanzania. In 2006, for example, the German Ambassador to Tanzania, Honorable Wolfgang Ringe, announced that the German Foreign Ministry had pledged 8.5 million Tanzania shillings to renovate the Maji Maji Memorial Museum (Chachage 2006). Given the fact that these are not given with a formal apology and acknowledgment of the crime and not paid directly to affected families, nothing is considered to have been done by the German government to the victims of the Majimaji war.

A

Future Directions

The Majimaji war is one of the catastrophes that fall within the realm of intergenerational historical trauma. It was a genocide, but obviously some genocides are prominently remembered, while others are ignored, hidden, or denied (Heerten and Moses 2014). The notion that local communities experienced genocide at the hands of their white conquerors is not only dismissed but openly derided by scholars because colonial and imperial wars are not usually considered genocidal (Dedering 1993). Nevertheless, the Majimaji war was meant to be destructive and genocidal because civilian population was systematically targeted: the entire villages, fields, and granaries were burnt, and hunger was used as a weapon to bring the guerrilla fighters to their knees. The Germans also committed cultural genocide by depriving the right to perform burial rite. In Tanzania, politics around the Majimaji genocide sprung in the parliament as awake to emulate the Kenya Mau Mau veterans and the Nama-Herero genocide. However, to delve into matters of the Majimaji as genocide, more research ought to be done: foremost to establish the exact number of people who died of the war, to document and bring to the fore all the genocidal acts committed during the war, and to repatriate human body parts which plausibly ought to have been taken from Tanzania.

Archaeology of the Massim Island Region, Papua New Guinea

Ben Shaw
University of New South Wales, Sydney, NSW, Australia

Introduction

Modern humans colonized New Guinea and Australia at least 50,000 years ago, which at this time formed a single continent known as Sahul. In the millennia that followed, descendants of these early inhabitants spread across this large mosaic landscape and eventually reached the eastern tip of New Guinea (northern Sahul) and the very edge of the continental world. Scattered off the eastern shores were groups of islands collectively known today as the "Massim region" (Fig. 1). The Massim islands have an ecological diversity substantially diminished compared to the continental landscape of New Guinea, and they have undergone considerable changes in size as global sea levels fluctuated throughout the Late Pleistocene (>12kya) and Early-Middle Holocene (12–4kya). Further to the east is the vast expanse of the Pacific Ocean, with the remote islands of the Pacific some of the last landmasses on earth to be colonized by humans. The Massim is therefore well positioned to inform on (1) how our species adapted to living in changing island ecosystems throughout the Late Pleistocene and (2) the long-term emergence of island cultures, prior to, during, and

Archaeology of the Massim Island Region, Papua New Guinea, Fig. 1 Map of (**a**) the Asia-Pacific region showing the location of the Massim in Papua New Guinea, and (**b**) the Massim islands, with those mentioned in the text labelled

after the colonization of the Pacific Islands ~3000 years ago.

The region is best known for the plethora of anthropological accounts describing indigenous island populations and the diverse aspects of their cultural systems, including Bronislaw Malinowski's famed 1922 ethnography on *Kula* exchange and Trobriand Island culture. Massim archaeology, however, is still emerging. Coverage of the islands is patchy, although temporal resolution of cultural sequences has greatly improved over the last decade. Archaeological research in

the Massim has been heavily influenced by anthropological cultural accounts which have provided a historical framework for understanding the deeper past. Because of this, research has predominantly contributed to our understanding of when, how, and why regionally distinct maritime-focused cultural identities developed, including the origins of ethnographically recorded trade networks and social systems.

Definition

The Massim Region: Geography, Climate, and Ecology

The Massim region defines the eastern tip of New Guinea and the adjacent offshore islands (Fig. 1). The islands are spread over 140,000km^2 of ocean, are situated 8–12° south of the equator, and range in area up to 1370 km^2 (Fergusson Island) and in elevation up to 2536 m (Goodenough Island). The islands are encompassed by the modern political province of Milne Bay, with the mainland including parts of the Central and Oro provinces. The modern population is ~300,000, although in the late nineteenth century, it was well below 100,000 and was likely lower throughout prehistory. Over 30 languages are spoken in the Massim, all of which belong to the Papuan Tip Austronesian subgroup, except that spoken on Rossel Island which is a non-Austronesian outlier not related to any known language (Ross 1988).

The islands can be divided geographically into northern and southern groups, which are separated by a deep-sea basin. Historical differences in human social practices further underpin this division (Seligmann 1910). Most of the islands are volcanic, with those in the southern Massim forming a discontinuous extension of the central mountain range which runs the length of New Guinea. Many low-lying coral limestone islands have uplifted on the shallow continental plate (e.g., Trobriand group) and in large barrier reef systems (e.g., Panaeati). The largest reef system (~8000km^2) encompasses many of the islands of the Louisiade Archipelago and is one of the most biodiverse marine systems in the world (Allen et al. 2003).

The Massim has a monsoonal climate comprising a marked wet (November–April) and dry (May–October) season. Prevailing winds blow from the southeast for most of the year, with northwest winds and cyclones prevalent during the wet season. Massim island communities rely on annual wind cycles to coordinate the planting and harvesting of garden crops, as well as long-distance sailing expeditions. The islands are near the equator with no major difference in temperature throughout the year, having an annual average of 26–27 °C. Rainfall varies considerably by topography as higher mountain peaks trap cloud more frequently, which has influenced the distribution of past and present populations. Low-lying (<200 m asl) islands receive 1500–2000 mm annually and high islands 3000–4000 mm. Despite having a relatively depauperate fauna compared to New Guinea, the Massim islands have a high proportion of endemic species, comprised mostly of birds, amphibians, and reptiles. Four ecozones broadly characterize the islands: Littoral foothills (>50 m), tropical lowland forest (50–1000 m), lower montane forest (1000–2000 m), and upper montane (2000–2536 m) forest. The majority of modern villages are situated within the lowest ecozone, though many late prehistoric and historic villages have been identified at higher elevations (Irwin et al. 2019).

Historical Background

European Contact

The earliest recorded account of external (European) contact with the Massim Islanders was by Spanish sailor Luis Vaez de Torres and his crew over 400 years ago, in 1606 (Shaw 2015). French sailors Louis Antoine de Bougainville and Antoine Bruni D'Entrecasteaux sailed through the region in 1768 and 1793, respectively, and named several of the islands. Extensive reef systems prevented European sailing ships from making landfall on most islands in the Louisiade Archipelago until the nineteenth century. The use of stone tools across the region declined throughout the nineteenth century as access to iron from shipwrecks and European trade became more commonplace (Bickler 1998). Europeans first settled on the islands in 1847 when Marist

(Original photos from Hamson and Aldridge (2009))

Missionaries established a station on Woodlark Island. Sustained European settlement was later established on Samarai Island in 1878 as a mission station and from 1888 as the district administration center following annexation of the region as a British protectorate. European cultural influences increased in the Massim after this time with a short-lived gold mining boom, the establishment of coconut plantations, and commissioning of several more mission stations.

Origins and Meaning of the Term "Massim"

The "Massim" is an anthropologically defined cultural construct with no explicit recognition of the term among local inhabitants, and it does not infer a common biological origin for the populations. The term was first used in 1856 by Italian Catholic priest, Father Carlo Salerio, to define a language spoken on Woodlark and other island, and is probably a phonetic mispronunciation of a local word, perhaps referring to the "Misima" language (Shaw 2015). Pioneering anthropologist Alfred Haddon (1894) adopted the term to collectively describe similarities between decorative designs observed on wood, shell, and bone carvings manufactured and widely traded in the region (Fig. 2). Charles Seligmann (1910) subsequently used "Massim" as a broader cultural nomenclature when he recognized a number of shared social aspects between the island populations, including matrilineal descent, the use of totems, and the organization of houses by clan affiliations. The term became firmly planted in anthropological literature following the publication of Malinowski's (1922) account of *Kula* exchange and is now used synonymously with "Milne Bay" when referring to the island groups off the eastern tip of Papua New Guinea.

The Kula Exchange Ring

No island group in the Massim region has received more attention from anthropologists than the Trobriand Island group, which was the geographic focus of the *Kula* exchange network (Fig. 3). The *Kula* is a vast institution involving the maritime exchange of shell valuables (*Mwali*

Archaeology of the Massim Island Region, Papua New Guinea, Fig. 3 The Kula Ring in the Massim. Major Kula communities are indicated by circles

armshells and *Soulava* necklaces) which circulate against each other clockwise and counterclockwise between exchange partners on different islands (Irwin et al. 2019). Participants who have the social standing to become involved in *Kula* gain prestige from successful exchanges through a process of delayed reciprocity, with a clear hierarchy both in the status of the valuables and between individuals involved. Although shell valuables are the primary items exchanged, food and other utilitarian goods moved through this network as the *Kula* also served to keep economic supply lines open between distant island communities during periods of drought and famine. Determining the prehistoric origins of the *Kula* network was the focus of early archaeological research in the Massim, discussed below in the Late Holocene section.

Late Pleistocene Settlement (17–12,000 Years Ago)

The Massim islands were colonized by modern humans at least 17,000 years ago, shortly after the Last Glacial Maximum (LGM) when sea levels were 110–120 m lower and islands were significantly larger. Air temperatures were only ~1–3 °C cooler than today due to the proximity of these islands to the equator and likely did not have any major impact on the diversity of vegetation on the islands (Rehfeld et al. 2018). Excavations at Kelebwanagum cave on the uplifted limestone island of Panaeati (30km^2) in 2018 revealed

burnt hard shore marine shell and small bird bone in the lowest layer associated with this age, indicating the inhabitants were primarily exploiting resources available in close proximity to the cave (Shaw et al. Forthcoming-a) (Figs. 4). During the LGM, Panaeati would have been almost ten times larger (~288km^2), providing a more substantial vegetation base and a larger shoreline with shellfish beds for pre-agricultural inhabitants to exploit. Obsidian (volcanic glass), also recovered from this context, has been attributed to the west Fergusson Island source, indicating people took lithics of known practical value with them as they dispersed into the more remote islands with an uncertain resource base.

Panaeati and the other islands of the Louisiade Archipelago had never been connected to New Guinea (Sahul), so watercraft and some degree of seafaring skill were needed to make the ≤17 km sea crossings. It is probable that people had also reached the easternmost Massim islands during the LGM as several robust "waisted" stone axe-adze blades were discovered on Rossel Island (Shaw 2017) (Fig. 5a). Although these blades were found in undated surface contexts, waisted tools are generally characteristic of Late Pleistocene sites across Sahul and are argued to have been used in early forms of plant management by ringbarking and felling soft trees, such as sago (*Metroxylon* sp.). A pre-LGM human presence in the Massim region is possible as waisted blades of similar dimensions had been recovered from excavations on the uplifted coral limestone terraces at the Bobongara site (Huon Peninsula) and date to >40kya (Summerhayes et al. 2017) (Fig. 1).

Early Holocene (12–8000 Years Ago)

There are no Early Holocene cultural sequences in the Massim, so little can be said about human activity during this time, although it was a period of marked environmental instability. Between 17kya and 8kya, postglacial warming rose sea levels ~100 m, which flooded coastal areas, reduced the size of shellfish beds, and drowned any established coral reef systems. The cessation of human use at Kelebwanagum cave by 12,600 years ago indicates people changed their settlement patterns and likely abandoned low-lying islands as they shrunk in size and ecological carrying capacity. Whether all of the islands were abandoned is not known, but only a handful of high islands would have remained large enough to sustain continual settlement of pre-agricultural populations. The increasing distances between islands would have limited the frequency of inter-island movement and promoted isolation, which may explain the genetic, linguistic, and cultural distinction of Rossel islanders from other Massim populations (van Oven et al. 2014).

Middle Holocene (8–4,000 Years Ago)

Evidence for Middle Holocene human settlement of the region is also scarce. The use of Kelebwanagum cave resumed by 4700 years ago, after a ~8000 year hiatus in human activity (Shaw et al. Forthcoming-a). The movement of people back into these islands during the Middle Holocene, as reflected by reuse of the cave, coincided with the stabilization of sea levels and the formation of large lagoon systems which are known in the region today. Exploitation of soft shore shellfish indicates that sandy beaches had formed on Panaeati Island, and the presence of small pieces of west Fergusson obsidian from this time onward suggests people were moving back into these more remote islands via the larger islands closer to the mainland.

The discovery of elaborately manufactured stone mortars, pestles, and tools (n= > 40) in the Massim suggests many islands were occupied in the Middle Holocene (Swadling 2016) (Fig. 5c–e). Although these stone tools all come from undated contexts, stone pestles and mortars are known in highland New Guinea archaeological sites and are putatively dated between 8000 and 3300 years ago. Their wide distribution, spanning the New Guinea Highlands, lowlands, and islands, is thought to have been part of an expansive trade network connecting communities across many language and cultural boundaries. A stemmed obsidian blade had also been found in the Massim (Fig. 5b), and these artifacts are known in the Bismarck Archipelago from contexts dating to 6000–3500 years ago (Fig. 6).

Archaeology of the Massim Island Region, Papua New Guinea, Fig. 4 Late Pleistocene settlement of the Massim. (**a**) Sea level curve over last 50kya, with red star indicating the earliest human settlement. (**b**) Size of landmasses in the Massim during the LGM, with location of west Fergusson obsidian source/s marked. (**c**) Uplifted limestone cliff on north coast of Panaeati Island near Kelebwanagum cave. (**d**) Kelebwanagum cave excavation in progress

Archaeology of the Massim Island Region, Papua New Guinea, Fig. 5 Possible Late Pleistocene and Early-Middle Holocene artifacts found in undated contexts on the Massim islands. (**a**) Waisted stone blade, Rossel Island. (**b**) Stemmed obsidian blade, Misima Island. (**c**) Stemmed stone blade, Trobriand Islands. (**d**) Stone pestle, Woodlark Island. (**e**) Stone mortar, Normandy Island

Most of these elaborate artifacts had been found on the larger islands of Kiriwina, Woodlark, and Misima, as well as the adjacent mainland. Swadling (2016) has argued their distribution may be related to the higher agricultural potential of these islands, which were likely important economic centers during the Middle Holocene. Currently, however, it is not known when agriculture was first practiced in the Massim islands. In the New Guinea Highlands, wetland cultivation of root and fruit crops was established by 7000 years ago, but in lowland and island areas, there is no clear evidence for agriculture prior to the arrival of the Lapita Cultural Complex into New Guinea from Southeast Asia around 3300 years ago (Summerhayes et al. 2017). A lack of earlier evidence for agriculture in the islands is due to the difficulty in finding sites where gardening evidence will have survived. It is possible that agriculture was established in the Massim islands during the Middle Holocene, as it was in the highlands, though confirmation is needed through archaeobotanical research.

Late Holocene (Last 4000 Years)

With the exception of Kelebwanagum cave, all archaeological sites in the Massim date to the Late Holocene.

Lapita Settlement (3050–2400 Years Ago)

Intensive settlement and the introduction of pottery to the Massim islands occurred by 3050 years ago and are attributed to the Lapita Cultural Complex. Lapita is an archaeologically recognized culture which introduced a number of significant new technologies, including pottery, developed island horticulture, several socially important animal domesticates (pigs, dogs, and chickens), and a more diverse range of shell ornaments and stone tools indicative of a well-defined hierarchical social organization. The earliest known Lapita sites are in the Bismarck Archipelago (Fig. 1). It is now clear that the Lapita settlement of the Massim islands was part of a large-scale diaspora of people out of the Bismarcks into the remote Pacific Islands and along the southern coast of Papua New Guinea around three millennia ago.

Archaeology of the Massim Island Region, Papua New Guinea, Fig. 6 Summary of Massim archaeology. (**a**) Major cultural phases since the Late Pleistocene. (**b**) Summary of Late Holocene island sequences since the apparent breakdown of the stone mortar, pestle, and stemmed blade cultural complex

Lapita settlement has been identified on three Massim islands: Brooker, Wari, and Nimowa. The Guntuka site on Brooker Island has yielded the earliest evidence and was occupied by Lapita communities from 3050 through to 2400 years ago (Figs. 6 and 7) (Shaw et al. Forthcoming-c). Shortly after the arrival of Lapita people on Brooker Island, a large volume of sediment was deposited on the beach from the adjacent hillside. The erosion derived from vegetation clearance as gardens were established on the hill. In addition to a presumably plant-based diet, the Lapita population on Brooker predominantly exploited reef fish (Scaridae) and sea turtle (Chelonioidea). Substantial quantities of obsidian were recovered, including retouched point and blade technology, indicating the Brooker population was in regular contact with those on or near Fergusson Island, from where the obsidian was sourced.

Lapita settlement on Wari Island (Kasasinabwana site) commenced from 2700 to 2450 cal. BP and on Nimowa Island (Malakai site) from 2400 cal. BP (Negishi and Ono 2009; Shaw et al. Under Review). The low density of material culture in the Lapita layers on both these islands suggests stilt houses had initially been built over a shallow lagoon, as only narrow beachfronts were present at this time. No obsidian was recovered from Lapita contexts at these sites, and it is possible they were "outposts" on the periphery of communication networks connecting major

Archaeology of the Massim Island Region, Papua New Guinea, Fig. 7 Pottery development in the Massim region over the last 3000 years

settlements on Brooker Island and elsewhere along the Papuan south coast.

Early Papuan/Massim Settlement (2400–1300 Years Ago)

Low-density settlement of the Massim islands continued after the Lapita period, although it is currently unclear if there was a decline in pottery production and use in the few centuries that followed. On Rossel Island, excavations at Mt. Yeme cave defined a cultural sequence spanning 2400–1600 years ago. While no pottery was recovered, its absence likely reflects use of the cave as a short-term shelter rather than a village settlement. Settlement associated with plainware pottery has otherwise been documented on Nimowa and Wari from 2100 cal. BP (Fig. 7). A richly decorated pottery assemblage has been excavated on Motorina Island, dating sometime between 2100 and 1200 years ago. Details of this excavation are not yet available, but on current evidence, the pottery is likely to be associated with the later end of this age range (Irwin et al. 2019).

The apparent loss of decorative motifs on Massim pottery suggests the symbolic social system once connecting Lapita settlements over several thousand kilometers had broken down, from which regional systems of social expression had begun to emerge. There is a marked similarity in the shape of pottery vessels in the Massim and on the south Papuan coast from 2100 to 1300 cal. BP which derives from having a shared ancestral history of pottery production since Lapita. However, pottery from several sites on the south coast spanning several hundred kilometers is intricately decorated with shell-impressed motifs, indicating close connections were maintained between these communities but not with those in the Massim islands. Pottery production and the social motivations influencing motif design were therefore likely to have been local to each region by this time.

Obsidian exploitation also supports this pattern. Fergusson Island obsidian was imported to Nimowa Island from 2100 to 1700 cal. BP and along the south coast until 1900 cal. BP (Shaw et al. Under Review). Very small quantities of obsidian moved over large distances from the source, likely reflecting down-the-line exchange between multiple communities. It was unlikely people were moving frequently over such large distances. Obsidian import to Nimowa did not resume again until 500 BP, suggesting that increased isolation of these remote islands contributed to the divergence of cultural development within the Massim and with the south coast.

Emerging Regional Social Landscapes (1300–500 Years Ago)

It is apparent that regular contact between island populations over the last millennia or so had facilitated the development of social systems unique to the Massim. One of the most remarkable aspects of this cultural landscape was the construction of large stone (megalithic) structures in the northern islands which spanned up to 800m^2 in area and are at least 1300–1100 years old (Fig. 8) (Bickler 1998). Their construction and use are broadly contemporary with the earliest forms of "Massim" art, as recognized by motifs on pottery and on intricately carved conus shell valuables (Ambrose et al. 2012). Equivalent megaliths are not known in the southern islands, and it can be inferred that there were fewer social connections between the northern and southern islands at this time than were noted in the nineteenth century. These structures were predominantly orientated to the cardinal directions, built in close proximity to major prehistoric settlements, and likely marked clan territories as part of a social landscape which spanned multiple islands. The construction of megaliths clearly required coordination of a large labor force and perhaps also reflects the emergence of a hierarchical social structure in the northern Massim.

The presence of deliberately interred human skeletal remains indicates the megalithic structures had a funerary function. They were used as a place for primary and secondary pot burials until 650–400 cal. BP, after which time the structural complexes fell into apparent disuse (Fig. 8). Within the last 400 years, caves and rock niches became more commonly used for the curation of

Archaeology of the Massim Island Region, Papua New Guinea, Fig. 8 Megalithic funerary structures on Woodlark Island. (**a**) 3D reconstruction of surveyed enclosures. (**b**) Primary burial of adult excavated within the enclosure. (**c**) Orientation of megalithic structures on Woodlark Island. (Images from Bickler (1998))

disarticulated skeletal remains, indicating that a major shift had occurred in how Massim communities viewed death and the deceased. Excavations on the Trobriand Island of Kitava revealed a cemetery with at least 17 individuals in primary burial contexts dated to 950–650 cal. BP. Although these skeletons were not interred within a megalithic enclosure, a similar shift to secondary cave burials had also occurred by 400 cal. BP (Burenhult 2002). After this time, the symbolic language connecting islands had broken down. A realignment of social systems is likely the cause, driven by rising population densities, competition over lands with high agricultural yield, and control over marine trade (Irwin et al. 2019).

Origins of the Kula Exchange Network (500 Years Ago)

At the Rainu mission station (Wanigela region, Collingwood Bay), several earth mounds were excavated, first by Rudolf Pöch in 1905 and by Brian Egloff in 1967–1969. The mounds contained substantial quantities of village refuse built up between 1100 and 500 cal. BP (Egloff 1979). Two broad cultural phases were identified based primarily on the stylistic analysis and chemical sourcing of the pottery. The Expansion Phase (1100–500 cal. BP) defined a period when villages in the Wanigela region on the New Guinea coast were supplying the D'Entrecasteaux-Trobriand Island groups with pottery. The Refuge Phase (<500 cal. BP) defined a subsequent refocus on inter-island trade, by which time the Rainu village had been abandoned and the Amphlett Islanders had completely replaced Wanigela as the primary pottery-producing center. It was argued by Egloff that by 500 years ago, the configuration of island connections reflected the ethnographically known *Kula* exchange network, thus providing a time depth to this historically important social system.

Key Issues/Current Debates

Timing, Nature, and Extent of Human Colonization

It remains unclear when humans colonized the Massim. The islands of the Bismarck Archipelago and the interior of New Guinea were colonized by modern humans from at least 44,000 cal. BP (Summerhayes et al. 2017). The Bobongara site on the eastern New Guinea coast was also occupied by 40,000 years ago. There is therefore a possibility that the Massim too was colonized as early as 40,000 years ago. Evidence of this antiquity would place these islands into global discussions about the adaptive processes of modern humans living in coastal and island environments. A current lack of clarity into Late Pleistocene Massim settlement is largely due to two reasons. The first is that the vast majority of archaeological sites earlier than 8,000 years are now underwater due to relatively rapid and substantial postglacial rises in sea level. Coastal areas will only have been preserved on islands with steep shoreline profiles or uplifted coastlines, such as was the case for Kelebwanagum cave on Panaeati Island. The second reason is that most archaeological investigations in the Massim have been aimed at identifying the prehistoric characteristics of ethnographically known social systems. As such, identifying Late Pleistocene settlement has not, until recently, been a priority of most field surveys.

Early and Middle Holocene Responses to Changing Island Environments

Archaeological sequences in the New Guinea Highlands have demonstrated an increased formality in stone tool technology sometime between 8,000 and 4,000 years ago, which includes the stone pestle and mortars found in the Massim. It is currently unclear if major changes in technology and settlement patterns occurred in these islands or if formally manufactured tools were transported to the islands from highland production centers. It has been argued, although not yet demonstrated archaeologically, that Lapita cultural groups arriving into the Massim utilized already established Middle Holocene coastal and inter-island networks (Swadling 2016). Sites found which date to this critical time period would yield significant new information on human adaptions to coastlines and islands which were undergoing significant changes and will provide insight into what social systems looked like prior to the arrival of Lapita cultural groups.

Lapita Settlement and Cultural Relationships with New Guinea, Australia, and the Wider Pacific

Over the last 50 years, archaeological research on the Lapita Cultural Complex has moved forward in leaps and bounds. Lapita sites are now known from New Guinea in the west to Samoa in the east, a distance of almost 5000 km. Advanced maritime technology was needed to cross these vast distance of open ocean, so the relatively small distances between the Massim islands would have been well within their technological and navigational capabilities. In New Guinea and the Massim, debate now surrounds (1) how Lapita communities interacted with already established populations that lived in these areas and (2) the extent of interaction between Lapita communities in neighboring regions. There is currently no clarity in the Massim on the former issue as no cultural sequences cover the period immediately prior to the arrival of Lapita. On the latter, there is some evidence for the interaction between Massim Lapita communities and with those further east in the Pacific. Fergusson Island obsidian has been found in 3000-year-old contexts in the Reef Santa Cruz and Vanuatu Lapita sites, and Lapita pottery in the Solomons has been tentatively sourced to Woodlark Island (Tochilin et al. 2012). It is therefore possible Massim Lapita communities played some part, directly or indirectly, in the colonization of the remote Pacific Islands.

International Perspectives

The Massim region is well-known internationally for the many anthropological accounts on island cultures. Comparatively, archaeology in the region has received far less attention, with the better known cultural sequences of mainland New Guinea having often been used as a proxy for prehistoric human settlement in the islands. The lack of longer-term archaeological records had prevented the regions involvement in broader discussions about the emergence of island cultures and on language and genetic diversity. This situation is beginning to change with an emerging Late Pleistocene archaeological record, but many chronological gaps remain to be filled.

Future Directions

As the resolution and time depth of archaeological records in the Massim continue to increase, more detailed questions can be asked about the role of these islands in the development of Pacific culture. Answering such questions will require multidisciplinary approaches to identifying change in language, material culture, biology, and the environment. Paleoenvironmental records are currently lacking for these islands. Coring of long-standing swamp and lake deposits will be crucial to understanding how sea level and climatic changes have impacted island environments and people's response to these changes. With an increased likelihood that many of the islands were abandoned and resettled since the Late Pleistocene, questions of population admixture and the effects of geographic isolation on population structure are becoming more pertinent. Genetic sequencing of prehistoric, historic, and modern islanders will be informative, but this must be done ethically and in consultation with local communities and governing institutions.

Archaeology of the Phoenician Colonies

Ana Delgado Hervás
Departament d'Humanitats, Universitat Pompeu Fabra, Barcelona, Spain

Introduction

Between the ninth and seventh centuries BC, people of Levantine origin began to move to other areas in the Mediterranean, where they would settle permanently. Most of these migrants came from cities and towns on the coastline of central Syria-Palestine, a territory known in some Greek texts as Phoenicia. Far from being a politically unified area, this ancient region was fragmented in a multitude of small and competing polities. The most important were Sidon and Tyre, two polities known internationally for their production of certain luxury manufactures such as dyes and textiles, but especially for their involvement in regional and interregional trade. The inhabitants of all these cities, whom the Greeks called Phoenicians, shared a common language and script, lived in the same geographical environment, performed similar ritual and funeral practices, and shared cosmologies and religious beliefs. Nevertheless, they never recognized themselves as members of a common ethnic or cultural group.

These Levantine' migratory movements were intense and multiple and involved the displacement

Archaeology of the Phoenician Colonies, Fig. 1 The Phoenician diaspora: main Levantine cities and overseas communities

of large numbers of people. Their migrations impacted many parts of the Mediterranean, most notably the island of Cyprus, the coastlines of modern-day Sicily, Sardinia and Tunisia, Ibiza and Formentera, and the coastlines of Iberia and the Maghreb (Fig. 1) as far as the Atlantic. These movements transformed the Mediterranean landscapes. Many of the newcomers settled in towns or ports previously inhabited or frequented by local groups, where they lived alongside the native peoples. In other cases, they founded new cities, small settlements, and ports of trade, as well as farms and rural places where they and their descendants formed hegemonic groups.

The term "Phoenician colonies" has traditionally been used to refer to the new settlements founded by these migrant communities in the western Mediterranean. Among them are the sites of Carthage, Utica, Mozia, Sulky, Ibiza, Malaka, Gadir, and Lixus, to name just a few examples. These settlements have traditionally constituted the main object of study in the discipline known as the archaeology of the Phoenician colonies. In recent decades, however, this perspective has broadened, thanks to the greater attention now being paid to the host territories and communities, and to the growing interest in the dynamics of connectivity and entanglement between the Levantine newcomers and the various peoples of the western Mediterranean. In fact, it seems fair to say that these new visions have shifted the discipline's focus of attention; scholars no longer center exclusively on the "colonies" and have begun to explore the landscapes of contact and hybridization that emerged from these experiences of mobility and migration.

Definition

The term "Phoenician colonies" refers to the new settlements created by groups of Levantine origin which moved westwards towards the rest of the Mediterranean and the Atlantic in the early first millennium BC. Nonetheless, the label is a controversial one; equally contentious is the concept of its derivate "colonization," conventionally used to describe these processes of mobility and the creation of settlements in distant territories.

The appropriateness of these terms to refer to the experiences of displacement of Levantine groups and the creation of Phoenician overseas communities began to be questioned in the late 1990s (van Dommelen 2012; see also Osborne

1998 for the ancient Greek diaspora). The criticisms held that the use of these terms generated anachronistic and biased visions of these migration experiences and, at the same time, helped to create a profoundly colonial body of knowledge regarding this past. The concepts of "colony" and "colonization," it was posited, have enabled colonial and Eurocentric views typical of the contemporary world to cross easily and uncritically into the context of the ancient Mediterranean; in this context, they have favored descriptions and interpretations of these processes and experiences that stress, on the one hand, the political, economic, and cultural subordination of the overseas communities to the Levantine homelands and, on the other, the superiority and dominance of the Phoenician newcomers over the host communities and territories.

Significantly, the founders or inhabitants of these overseas enclaves never spoke of "colonies"; the term was in fact coined by Latin authors who used it in their accounts written several centuries after the establishment of Levantine communities in the west, transferring concepts from the Roman world to distant, alien environments. In the Roman Empire, the term "colony" referred mainly to settlements or farmsteads awarded to army veterans in the conquered territories, where they became outposts in defense of the Roman territory. The term also designated cities located in distant lands that enjoyed special political status and acted as strategic enclaves for the deployment of the empire's cultural, economic, and military policies. These meanings were then passed on to the modern European world, where the Latin word "colony" was used to refer to overseas plantations and settlements whose inhabitants were subject to European states, and which helped to execute policies of economic exploitation, cultural dominance, and/or military control. The circle was completed when Mediterranean archaeology indiscriminately incorporated the terms, along with others such as metropolis or colonial system; in doing so, they transferred relations, practices, and experiences of modern-day colonialism to the Mediterranean and Atlantic world of the Iron Age.

In recent decades, however, the archaeology of the "western Phoenician communities" has allowed scholars to piece together an enormously complex panorama of experiences and dynamics. This new perspective is now challenging the simplistic, traditional visions based fundamentally on the sparse information transmitted by classical accounts *and read through the colonial lens* of the western modern thought.

Historical Background

At the dawn of the first millennium BC, products, aesthetics, know-how, and social practices that are conventionally defined as Phoenician reached the western end of the Mediterranean world. The oldest evidence of this flow of knowledge, ways of doing things, and material cultures has been recovered in south-western Iberia, beneath the modern-day city of Huelva, an active hub of connections since the tenth century BC occupied by local groups and located near rich mineral resources, mainly silver and copper. At this site a dozen transport jars of "Phoenician" typology dated to the end of the tenth century BC have been found (González de Canales et al. 2004). Their small number suggests that these connections were only sporadic, but their presence nonetheless reflects the emergence of a new trend in the mobility of Levantine material cultures and/or people across the Mediterranean.

The authentic transformation of these processes took place during the ninth century BC, especially during its final decades. At that time, connectivity and maritime mobility across the Mediterranean region grew significantly in terms of its intensity, volume, extension, and regularity. Over the course of the century, Levantine peoples gradually took center stage in these connections that crossed the entire Mediterranean and moved large quantities of people, products, practices, and technologies. Archaeological and textual evidence indicates that the polities located in the south of present-day Lebanon – such as Sidon, Akko, and especially Tyre – had a hegemonic role

in the management of this incipient sea connection (Gilboa et al. 2015; Aubet 2001).

Evidence of Levantine cross-Mediterranean mobility in the ninth century BC is concentrated in specific areas: Cyprus and southern Crete, areas in central Italy and along the Tyrrhenian Sea, Sardinia, the coast of Tunisia, and southern and south-western Iberia. The evidence begins to be more intense in the last decades of the ninth century and the beginning of the eighth. From this period, Levantine cooking pots, hybrid technologies, or ritual practices have been found that bear witness to the settlement of "Phoenician" people in western lands, either permanently or for long periods of time. These early settlements have been documented in enclaves such as Kition, Kommos, Utica, Sulky, Sant'Imbenia, Carambolo, Rebanadilla, and Huelva – all local settlements or trading posts where the presence and activity of local groups was predominant or particularly significant. They are all located in strategic sites in the Mediterranean maritime connections and, in some cases, have easy access to rich metal resources, especially copper and silver. The archaeological record of these enclaves suggests that groups or small trading communities were set up, comprising people of different origins and cultural backgrounds. In some of them, the Levantine groups were the majority.

The site of Huelva bears especially eloquent witness to these practices. Thousands of vessels traditionally labeled Phoenician have been recovered in this Atlantic port. Some are from the beginning of the ninth century BC, but the vast majority are more recent, dating from the end of the ninth century and the beginning of the eighth. In this period the traces of these connections in the archaeological record increase significantly, although radiocarbon dating yields somewhat older chronologies. The "Phoenician" objects recovered in Huelva comprise mainly tableware, containers, and transport jars (i.e., merchandise used in trade) but the presence of kitchenware alongside these tradeable items indicates that people from the Levant had indeed settled there (Delgado Hervás 2017). Together with this evidence of everyday activities, there is a large presence of production waste, especially of minerals such as silver, but there also traces of ivory carving, tools for making jewellery, writing tablets, and weight sets. These materials clearly reflect the presence of enclaves of people who mastered the technologies and know-how of the Levantine tradition – merchants and craftsmen who produced a large proportion of the goods that the locals required. Other articles, technologies, and practices suggest the importance of the local groups in this port and a minority presence of other Mediterranean people, such as Sardinian groups.

In the first half of the eighth century BC (or slightly earlier, according to radiocarbon dating), this new dynamic of cross-Mediterranean movement of Levantine groups intensified, and their strategies, settlement modes, and overseas lifestyles began to change. The number of migrants moving to the west at this time grew exponentially, and for the most part their settlements became permanent. These migratory movements, which began in the late ninth/early eighth century and lasted at least until the beginning of the seventh, are part of the Phoenician diaspora traditionally known as the Phoenician colonial expansion to the west.

In these western areas, the new migrants implemented a range of settlement strategies. Some of them, for instance, the groups that settled in areas of south-western Iberia or in Sardinia, did so among or alongside local communities, a strategy that resulted in particularly entangled social and cultural configurations (Arruda 2009; Roppa 2019). At the same time, other Levantine groups founded new settlements in the west, creating new centers either in previously uninhabited places or in spaces frequented or occupied by local groups in earlier periods. In both cases they constructed built environments, sacred places, cemeteries, and domestic spaces that broadly reproduced Levantine landscapes and lifestyles. These centers are traditionally known in the archaeological literature as Phoenician colonies. The material cultures, and especially the various ways of acting and doing

things that are recorded in these sites, suggest that these communities comprised people from diverse backgrounds: along with descendants of the people of the Levant we also find groups of local origin or from elsewhere in the Mediterranean and the Atlantic, with a notable level of coexistence and hybridization (Delgado Hervás and Ferrer 2012; Guirguis 2019). This is also suggested by genetic evidence recently obtained from DNA analyses in western Phoenician and Punic cemeteries (among others, Matisoo-Smith et al. 2018).

These communities formed small geographically dispersed enclaves, without any links across land but closely connected by sea. The main western Phoenician communities basically spread around two main seascapes: the first around the Strait of Gibraltar, embracing part of the Atlantic and Mediterranean coastlines of Iberia and the Maghreb, and the second in the Central Mediterranean, extending around the maritime triangle formed by the coast of Tunisia, the western tip of Sicily and southern Sardinia. These two archipelagos or clusters of Phoenician peoples maintained close connections with each other. Their communities shared language and script, lifestyles, material cultures, and ritual practices; but from a very early stage they also presented significant divergences, expressed in their settlement modes, their domestic spaces, their symbolic universes, and their funeral practices.

The first of these clusters, located in the area of the Strait of Gibraltar, comprised a large number of Phoenician communities living in newly created settlements or in local towns where sometimes they set up their own neighborhoods. The concentration was especially intense on the coast of Iberia, where numerous settlements dating between the end of the ninth century and the end of the eighth century BC have been found. The excavations carried out in these settlements have shown that the newcomers recreated built environments and domestic spaces of Levantine type and that from the end of the ninth century BC they built small cemeteries in the vicinity of some of these sites, often apparently for particular families, reflecting their will to create ancestral ties and memories in the new territories (Delgado Hervás 2017). The newcomers mainly settled by the sea, at sites such as La Fonteta, Morro de Mezquitilla, Rebanadilla-Cerro del Villar, Gadir, Doña Blanca, Carambolo, Huelva, and Lisbon, to name just a few, but there were also inland enclaves like Carmona. In the African lands below the Strait the Levantine diaspora had a lower demographic impact; although Near Eastern-style housing complexes have been excavated in Lixus, few Phoenician communities from these early stages are known here (Aranegui et al. 2011). It was in the seventh century BC that the presence of western Phoenicians in north Africa began to make itself felt.

Inside this cluster of Phoenician communities and people created around the Strait of Gibraltar, the settlement of Gadir stands out. Recent excavations carried out beneath the modern-day city of Cádiz (Botto 2014; Niveau de Villedary 2018) have revealed a first permanent Phoenician settlement, founded between the end of the ninth century and the beginning of the eighth century BC. The settlement was established on a group of islands off the Atlantic coast of Iberia, recreating the seascapes and lifestyles of Levantine cities like Arwad or Tyre (in fact, the close links between this last polity and Gadir are mentioned in the classical sources). Streets, domestic spaces, kitchenware, and even certain animals such as pet cats recall landscapes of the Mediterranean Levant, despite the clear signs of entanglement with local and other Mediterranean people, above all local but also Sardinian people, reflecting a multiethnic and multicultural community. The first houses of Gadir and the material evidence recorded in them indicate that migrant family groups (and not just male adults) played a major part in these experiences of mobility, as well as in the economy and in the trading activities from the earliest stages of the settlement (Delgado Hervás 2017).

However, the uniqueness of Gadir lies not in its residential areas but in its sacred landscape (Niveau de Villedary 2018). The concentration and the extension of funeral areas recorded is unknown in other Phoenician sites in and around the Strait, as are the number and the type of sanctuaries and religious practices hosted by this

small archipelago. Gadir was home to as many as three important sanctuaries built in archaic times, the most important of which is probably the temple dedicated to Melqart, the main deity of Tyre. Today, the roles of Gadir and this sanctuary at the westernmost point of the Phoenician world are the subject of controversy. Some researchers regard the town as a commercial metropolis and the temple of Melqart as a representation of the Tyrian state in the west, where it would have acted as a base for expeditions and for controlling flows of trade and business (Aubet 2001). Others, distancing themselves from these stereotyped views, have highlighted the symbolic and religious significance of Gadir in this western Phoenician cluster (Bonnet 2009); accordingly, Gadir and its temple of Melqart would be key features in the construction of a new identity in these communities born of migration and entanglement, keeping alive the memories of the diaspora and the link with the homeland.

The numbers of Levantines arriving in the central Mediterranean area and settling permanently also increased as the eighth century BC progressed. Together with settlements in local centers, new establishments were also founded. The latter exhibit material cultures, architectural designs, and lifestyles predominantly of Near Eastern type which bear witness to settlement by Levantine groups. At the same time, certain habitus and traditions related to Sardinian, North African, Sicilian, and even Iberian groups are detected. This entanglement of material cultures and ways of doing things suggests the presence of mixed communities (Guirguis 2019). On these coastlines the number of new settlements seems to have been lower than further west, but, nevertheless, from the seventh century BC these nuclei had populations that were far larger than those of the Phoenician settlements in Iberia. Likewise, their built environments and the size of their cemeteries and sacred areas indicate lifestyles of a purely urban nature that were not known until later in the Phoenician areas further to the west. An example is the settlement in Motya, established on an islet off the coast of Sicily. The arrival of people from several Levantine areas in Motya has been dated to the first half of the eighth century and is associated with contexts of a sacred nature. At the end of the eighth century and the beginning of the seventh, large numbers of people involving mixed groups from Syria, Phoenicia, and the Philistine region arrived in the island; they built large residential areas and workshops, as well as extensive cemeteries and sacred areas, among them a tophet (Nigro and Spagnoli 2017).

Carthage emerged as the greatest urban settlement of the Phoenician cluster as it spread across the Central Mediterranean. Its Phoenician name, Qart Hadasht, means "new city" and refers precisely to the foundation of a new city, as reflected in a famous founding myth that links its creation with people from Tyre. Its oldest archaeological levels have been dated to 760 BC, but the radiocarbon dating indicates an earlier occupation, at the end of the ninth century BC (Docter et al. 2005). From its early days, the city grew quickly and developed a complex structure: it is estimated that in the seventh and sixth century BC it could have covered an area of 25 ha and had a population of between 5000 and 8000 inhabitants (Telmini et al. 2014). Some of the cemeteries surrounding the city were built the eighth century BC. Their ritual and funerary expressions were deliberately conservative, reflecting a trend also found in other Phoenician areas of the Central Mediterranean. Several authors have suggested that these ritual practices played an important role in the construction of a common identity within communities marked by mobility, ethnic heterogeneity, and cosmopolitanism. The tophet, a sacred site dedicated to the cult of Baal Hammon and Tinnit where remains of animals and young children were deposited as offerings, seems to have had a special significance in the emergence and expression of this identity (Bonnet 2011; Quinn 2019).

Key Issues/Current Debates

The archaeology of Phoenician colonies is a relatively new field of study in Mediterranean archaeology. The discipline was created in the 1970s thanks to the work of Sabatino Moscati and

other pioneers. Since then its study has centered mainly on defining and analyzing the processes of displacement that gave rise to the creation of Phoenician settlements in the west. Special emphasis has been placed on determining the chronology of the first westward movements of people from the Levant and establishing the reasons behind them and also on characterizing the settlement modes of these migrant communities.

The chronology of the first movements of Phoenician groups to the west been a controversial issue especially since the 1990s, when radiocarbon analysis was used broadly to date Phoenician settlements or local Iron Age contexts with Phoenician materials. The calibrated radiocarbon dates showed a mismatch of some 50 and 100 years with respect to the conventional dating obtained from the study of ceramic typologies, which is based on a system that crosses and compares different Mediterranean ceramic sequences (López Castro et al. 2016). The focus on the chronological debate has distracted attention from other areas of the discipline that remain largely unexplored; but establishing the time frames of the diaspora is essential for a reliable characterization of their first movements and for an appraisal of their causes and the motivations of their protagonists. The chronological imprecision leaves an important question unanswered: did a series of the disconnected migratory movements act as drivers of the diaspora, each one with its own causes, motivations, and characteristics; or was it a single protracted movement that was the result of a projection and planning imposed from the top?

Top-down perspectives are predominant in Phoenician archaeology. They tend to categorize the movement of people or objects from the Levant recorded during the tenth and ninth centuries BC as projects of exploration or pre-colonization designed to locate areas for trade or for the exploitation of raw materials, especially metals. They argue that these voyages, which would eventually culminate in the creation of permanent trading communities, would have been led and sponsored by the aristocratic houses of the Levantine polities, headed by the royal houses themselves. Some authors define the so-called Phoenician diaspora or colonization as a directed, organized, and structured movement run mainly by the Tyrian state to generate new wealth through trade and the extraction of raw materials (especially silver) to meet the demand in the great states and empires of the Near East (Aubet 2001).

These top-down analyses tend to transmit a vision of the elites that is embodied in the few available written sources. But they are not always borne out in the archaeological evidence of the western scenarios. This evidence shows that the "Phoenician diaspora" has tended to be oversimplified; it suggests that there were different and long-standing experiences of mobility, which were inspired by wide-ranging and even contradictory motives. Likewise, the archaeological data indicate the prominence of multiple agencies, both in the displacements along the Mediterranean and in the processes of creation of the western Phoenician communities. One of the most important of these agencies was that of the certain western Mediterranean groups, among them people from the southwest of Iberia, Sardinia, and North Africa who played a particularly prominent role (Delgado Hervás 2017; Botto 2014; Guirguis 2019).

The relationship between newcomers and local groups, and the impact caused by the arrival of peoples from the Levant on the landscapes, material culture, and lifestyles of the Mediterranean, is among the focal points of the discipline. These topics have traditionally been explored via approaches of acculturation or center-periphery models focusing on the circulation of manufactures and raw materials between local elites and Phoenician merchants, and interpreting it mainly through the lens of prestige goods systems. In recent decades the influence of postcolonial thought has given way to new perspectives that stress concepts such as entanglement or hybridization (van Dommelen and Rowlands 2012). These new

approaches recover the voice of the local people in the construction of their own histories and highlight their agency and participation in the creation of the western Phoenician communities. These perspectives, however, have marginalized key issues in these "encounters" such as conflict or power relations. The focus on the heterogeneity of these areas, on the other hand, has raised the interest in issues of identity construction and community building, topics that have been explored through everyday practices and material cultures (Delgado Hervás and Ferrer 2012; Roppa 2019) and, in particular through ritual (Bonnet 2009, 2011; Quinn 2019).

Critical perspectives have recently questioned the use of the term "Phoenician," understood as an ethnic identity in the modern sense, that is, as a self-ascribed regional identity (Quinn 2019). The central argument is based on the absence of any terms that express a common identity shared by the inhabitants of the polities that the Greeks called Phoenician. Accordingly, the term corresponds to an expression of an etic type (that is, from the view of an external observer) rather than an emic one. Thus, the discourse analysis method has entered Phoenician studies and has done so with the aim to deconstruct the archaeological concept of "the Phoenicians" that Sabatino Moscati created in the 1970s. This recent critical look, woven basically from the classicism, has been harshly answered from influential sectors of the Phoenician archaeology (Oggiano 2019).

International Perspectives

The archaeology of the western Phoenician colonies or communities is, by its very nature, a translocal and transnational subject. The mobility of people, material cultures, and know-hows traditionally labeled Phoenician affected practically all the regions of the Mediterranean, as well as areas of the Atlantic located at its limits. The Phoenician diaspora took many different forms, ranging from simple, indirect, and occasional contacts to full-scale settlement in small enclaves, rural areas or cities. In other areas of the Mediterranean, their entanglement or hybridization with local groups was so intense that it is extremely difficult to trace separate, clearly defined identities or territories. The mobility of some of these peoples, their material cultures, and their lifestyles gave rise to new connected seascapes inside the Mediterranean area. Transposing present-day terms onto this historical past, these connections have sometimes been interpreted as a first Mediterranean "globalization." Whatever the case, the ways of life of these peoples established them as key agents in the process of Mediterraneanization that the inhabitants and the regions of the Mediterranean basin experienced, in different ways, throughout the Iron Age.

The wide geography of Phoenician archaeology has attracted the attention of archaeologists all over the world, although the most powerful academic centers of the discipline are in Mediterranean countries. Although researchers tend to focus on specific regions and sites, the translocal character of the core issues of the discipline has favored an intense dialogue between researchers working in different countries and regions. This dialogue has been continued in international research and heritage projects involving teams formed by researchers from different countries, and at frequent international meetings and conferences such as the International Congress of Phoenician and Punic Studies.

Future Directions

The incorporation of new methodologies from the archaeological sciences is one of the most important future directions in the archaeology of western Phoenician communities. These methodologies will provide quality evidence that will shed new light on some of the discipline's main concerns. Some projects have already embarked on this route and have

incorporated the study of ancient DNA and stable isotopes to analyze patterns of the mobility and migration of people (and also of animals) across the Mediterranean. This evidence opens up new horizons for analyzing issues that remain practically unexplored at present, such as family relationships, diet, breastfeeding and child care, or the impact of the introduction of new plants and animals on production economies and the landscape. Along with these methodologies, the analysis of organic remains contained in ceramics will provide new materials for the study of the production, mobility, and consumption of certain substances and their use in diet, care, or ritual practices.

Some of these methods from the archaeosciences will have an important impact on the study of topics related to the social life of these people and communities. The themes have been practically ignored in Phoenician archaeology, which has focused its attention on the study of chronologies, trade, and ritual. Topics such as domestic and everyday life, households and families, work, landscape and rural life, gender and infancies, minority groups and ordinary people, and power and conflict are some of the future directions for the discipline to explore. Together with these new themes and methodologies, the decolonization of the discipline's practices and discourses is also an important line of future research.

Archaeology: Definition

Soren Blau
Department of Forensic Medicine, Victorian Institute of Forensic Medicine, Monash University, Southbank, VIC, Australia

Archaeology comes from the Greek term *arkhaiologia* meaning "the study of ancient things" and is defined as the study of past peoples and culture. Archaeologists develop interpretations about the past through the recovery and analysis of material culture (which may include graves, monuments, buildings, inscriptions, tools, pottery, etc.) and associated evidence (such as pollen, charcoal, residues, skeletal remains, etc.). In order to provide interpretations about the past, archaeologists must accurately recover and record all aspects of a site.

Archaeologists may study the recent (historical) or distant past and are interested in a diverse range of subjects including how humans organized their social groupings and interacted with and/or exploited the environment, living conditions, diet, health status, trade patterns, and burial choices to name a few. For this reason, archaeologists may have specific areas of expertise which could include the analysis of specific material culture (e.g., pottery), environmental samples, human and or nonhuman skeletal remains, dating techniques, and so on.

State of Knowledge and Current Debates

Introduction

Archaeology as a social science is no stranger to the time in which it develops; therefore, it is constantly changing in its objectives and procedures. Similarly, it is not uniform, its development and practice are the function of its practitioners, and it relates to political and economic powers of every age and their interests. This eventually ends up forming dominant or official groups within the discipline that do not always coincide with the best of science or with what archaeology can do as a social science.

So although archaeology as a discipline starts emerging in Europe in the nineteenth century, the archaeology of the nineteenth century (the archaeology of capitalism or colonialism) starts at the end of the twentieth century. Industrial archaeology is one of the newest branches of archaeology, which is dedicated to the study of sites, methods, and machinery used in production processes introduced with the Industrial Revolution and the forms of social behavior and habitat resulting from such change. The term "industrial archaeology" arose in England and goes together with the concept of industrial heritage (Vincenti 2007). The overall aim is to go beyond written documents and graphics, but with diverse interests and approaches: for example, not with history as auxiliary but contrasting with what is believed to be known according to historiography, contributing to the explanation of the process of globalization that starts at this historic time. This archaeology has been practiced as an alternative to the study of documents of the Industrial Age, which have revealed biased in favor of the ruling classes and insufficient at allowing reliable research on the life of the subordinate classes, the peasantry, marginalized minorities (the end of African American slavery, aborigines from different parts of the world, communities or religious or political minorities). The starting point assumes that archaeological data not only allows the opportunity to balance the information but also to verify the truth or falsity of what the documents say and identify the discrepancies between them. It has therefore been the archaeology of capitalism, gender, "the border" – that is, the contact of the indigenous with settlers (with different approaches: the duality of domination-resistance and creolization or mestizaje).

Even the nineteenth century is investigated from archaeology with the aim of restating scientific methodology itself and revealing its biases (from feminism, for example) or searching for (pre)supposed incapacities and limits of archaeological methodology. Finally, it is being considering an archaeology of the modern era with profitable interest into what will be called industrial landscapes/industrial heritage, with industrial tourism routes included, especially in Europe, or to reclaim the recent history of other continents (from a vision of Native peoples not as a distant past, or as "acculturated passive" indigenous).

Although this nineteenth century archaeology began in Europe, in the same way as prehistoric archaeology, it rapidly spread to the USA and to areas that were colonized or industrialized in the nineteenth century: Australia, Central and South America, the Caribbean, Africa, and Asia. There are at present international journals, as well as Industrial or Historical Archaeology societies in different countries that publish journals and monographs where a large amount of information can be found. Its variety of approaches, objectives, and praxis are causing the various denominations within this Archaeology: historical, of capitalism, industrial, urban, ethnoarchaeology, colonial archaeology.

Global Perspective

Tierra Del Fuego Hunter-Gatherer-Fisher Societies

In this context, in 1988, a Catalan research team with Argentine collaboration began an ambitious ethnoarchaeological program in Isla Grande,

Tierra del Fuego. The shores of the Beagle Channel had been until the late nineteenth century an important part of the territory of aboriginal groups considered canoeists, namely, the group that the Austrian ethnographer Martin Gusinde had called *Yámana*. The aim of the project was basically methodological and ethnoarchaeological:to test the possibilities of modern archaeological methods to elucidate the nature of social relations that organize a hunter-gatherer society. In order to do this, excavations were carried out on sites that were last occupied by those societies, when they had already had contact with Europeans and were well documented and described. That is, eighteenth and nineteenth century Aboriginal settlements located on the coast of the Beagle Channel were excavated, and as an element of comparison, the northernmost settlements in the interior of the island corresponding to other native groups, called selknam by ethnographers, were also excavated. These were the yamana sites of Tunel VII: a settlement/hut with ten successive occupations; Lanasuhaia: settlement with a prolonged occupation of several months (Fig. 1); Alasawaia with the excavation of consumption remains of the last occupation of a settlement; Harberton, a midden shell burial of an adult (male); Mischiuen III a burial of an adult female in a rockshelter (reused as a burial area) and Cabaña Remolino, a site which hosted one of the last yámana ceremonies according to Gusinde, and in the heart of the island, the selknam sites of Ewan I a ceremonial hut and Ewan II, a hut with an occupation related to the one mentioned before.

The results of the above work allowed the archaeological documentation of the last moments of these societies and the causes of their disappearance (Estévez and Vila 2007).

These canoeist Aboriginal groups, whose history in the area dates back to 7000 years ago, lived in the nineteenth century (first half) basically exploiting coastal and marine resources (fisher-gatherer-hunters). They had a technology that today is described as simple with rigid social norms that maintained structural inequality between women and men at all levels. Previous archaeological work had shown that after a long historical process, a social organization had been achieved, which held control over food and consumer goods production as well as over biological reproduction.

With the archaeological evidence of the studied sites, the first indirect contacts with Europeans/whites were found. Shortly after the first European expedition passage through the Strait of Magellan in the sixteenth century, European raw materials had reached the area of the Beagle Channel (a fragment of glass in Recent Component Lancha Pakewaia site, 250 years BP at least). This means that the first indirect

Archaeology: The World at 1800–1850, Fig. 1 Lanashuaia archaeological site in Tierra del Fuego (Argentina)

European influence came 200 years before the first official expedition, the HMS Beagle.

In the nineteenth century sites, European materials are already present, although in small quantities (glass fragments) or have indirectly been documented through cutting marks left by metal instruments in some large animal bones. This European presence only involved changes in the raw materials used in their technological system, improving efficiency level: For example, glass or iron found on beaches from ships or shipwrecks was used to replace the mussel shells as knife blades or arrow stone heads and fragile bird bone awls. Initially, these new materials were worked with the same methods used for local raw materials (percussion, abrasion, polishing) and they were even given shapes that imitated traditional forms (awls are European metal nails shafted in bird long bones such as the traditional awls, the European iron blades are hafted transversally like the aboriginal mollusks-blade knives.) (Fig. 2).

Perhaps due to the fact that the archaeological sites are not yet fully documented at an extensive level, substantive changes either at settlement or social organization levels have not been observed as yet. Big changes are only confirmed later (in the second half of the nineteenth century), when there is written information of missionaries who settled in the area. Hut remains of the contact time do not differ from those of previous ages, although it is possible that at the time of the proto-contact and first contact, there were hut settlements formed by larger groupings of those described from the second half of the nineteenth century. This could be the case at the Lanashuaia site, and also of the camp sites that can be observed in the engravings of the first expedition to Cape Horn.

European Diseases

Although the first impact of diseases is not known, it is likely that new diseases and new outbreaks of existing ones, and which are archaeologically verifiable in human remains, drastically diminished the number of people. On the issue of diseases, we do not know the impact of those that could be transmitted at a distance, before the actual arrival of Europeans. However, there are documented infections that occurred from direct contact, although there are no written records until later when the missionaries had settled, who described episodes of mass mortalities. It is therefore possible that the ethnographic image constructed from the second half of the nineteenth century offers a different humanscape that could have originally existed in the time prior to European contact.

However, not enough human remains of those times have been analyzed yet, even though there are already enough excavated: a burial in a midden of an adult with two glass scrapers in Harberton, a young woman in the rockshelter Mishiwen III, near one of the first settler-

Archaeology: The World at 1800–1850, Fig. 2 Fueguian knives: the two to the *left*, traditional making with mollusk valve blade, the three at the *right* using European iron blades hafted in the traditional way

missionary settlements, or a burial in Acatushún midden, with an adult and six buttons associated.

However, it is known that there were direct contacts with crews of whaling ships and fur-sealers, crews with scientific and political expeditions, and later missionaries who actually not only introduced new diseases but favored certain everyday practices that negatively affected the health of the indigenous population.

At this time, the practice of abduction and translocation of indigenous people also began, which continued into the twentieth century. By 1829, during the first trip for scientific exploration of the South American coast, Lt. British Royal Navy Robert FitzRoy took three native young men and a girl from the coasts of the channel to Britain in the brigantine Beagle (Fueguia Basket, Jimmy Button, York Minster, Boat Memory). And in 1831–1836, the same FitzRoy now Commander on the second voyage of the Beagle (which is famous for the travel journal published by Charles Darwin) brought back the three surviving Fuegians: Fueguia Basket, Jimmy Button, and York Minster.

Christian Missions

It was on this 1836 journey, that the first failed missionary attempt occurred: Richards Matthews, appointed by the Church Missionary Society to remain among the Fuegians, stayed a few days at Wulaia Bay (now Chile) but resigned and returned to the ship. Later, in 1848, the second missionary attempt would take place, by Allan Gardiner in Picton Island (the mission failed and afterward the human remains of the first missionaries who died of scurvy and hunger were rescued). It was not until 1871 that the Anglican mission of Thomas Bridges and his family (Mary Ann Varder and her daughter) was definitively established in the channel. This first stable mission, a small village with farm gardens would become the modern city of Ushuaia which has not been excavated, nor have subsequent missionary settlements in the area.

Predation and Overexploitation of Native Resources by Europeans

One of the phenomena that excavations in Tierra del Fuego have shown is the relative and significant increase of fish remains together with the decrease in the proportion of sea lion consumption in these eighteenth and nineteenth century settlements (Tunel VII, Lanashuaia, Alasawaia) compared with their presence at sites of previous eras. It was interpreted as evidence of an frustrated attempt to change the strategies of subsistence. The pinnipeds resource had been one of the keys to maintaining the livelihood of these peoples, since the last breeding areas of these animals were in the outer islands and the Antarctic Ocean, away from the technological range of the indigenous population. So the intensification of fishing could be an attempt to develop an alternative resource against a continually descending abundance of pinnipeds. However, it is very likely that the rigidity of social norms, the catastrophic effect of diseases, and the scattering of the population, together with the subsequent missionary activity, did not allow a possible slow structural change, but precipitated the disintegration and dissolution of the native society.

It has been shown that even though the paleoclimatic record found at archaeological sites shows slight variations throughout the Holocene, there was not a natural biotic or abiotic cause to explain this final disturbance.

In the early nineteenth century, Euro-American seal and whale exploitation began in the Antarctic, although there are not yet too many historical details about its magnitude, temporality, dynamics, and intensity. However, in the 1990s of the twentieth century, archaeological projects were initiated in the Antarctic confirming the assumptions made about the causes that affected the issues mentioned before. Indeed, the whaling settlement excavations confirmed documentary sources pointing to a constant presence of sealers and whalers fishing boats directly slaughtering in the breeding zones with technologies much more lethal than the ones of the natives. This caused the catastrophic decline of marine mammals, a fundamental element in the diet of the canoeing people of the Fuegian archipelagos.

Archaeological excavations of camps and sealer shelters in Desolation Island and Cape Shirreff (South Shetland Islands) provided the first physical evidence of the coexistence of

foreign and indigenous hunters, demonstrating that these boats used male natives as workforce/sailors/pilots and women as sex objects. All of these contributed to the disintegration of native social organization. In the archaeological sites, indigenous artifact remains were found in direct association with remains of wood, ceramics, earthenware, iron, glass, and seeds from English or American origin of the nineteenth century. In Yamana Beach, close to two rockshelters that were used by sealers, a complete skull of a young mestizo adult woman and two femurs, apparently from the same person, were found.

It was also found in other beaches a marked architectural difference between settlements and, in some cases, constructive differences which are attributed by researchers to persons of different status within groups.

Since there is no radiometric method that could be applied to these archaeological findings reliably, the exact chronology is a problem. Consequently, due to the high homogeneity exhibiting archaeological materials and knowing that the first stage of hunting, between 1819 and 1825, was the most intense of all and which brought the largest number of hunters, there is a tendency to ascribe the findings to this moment. Furthermore, the type of pipes present in these sites strongly reinforces this assumption, since the pipes found in the sites are from the 1780–1820 period (Stehberg 2003: 177).

Another interesting archaeological project in this regard is the Spanish-Chilean project that sought the location of the Spanish ship San Telmo, considered as being lost in South Atlantic waters of Cape Horn in the spring of 1819 when it was sailing from Cadiz to El Callao, in the American coast of the Pacific Ocean (Stehberg 2003). It was sent together with three other ships and troops to try to help the Spanish royalists in the rebellious colonies in South America.

The archaeological study included not only the search and identification of the ship remains but also all evidences left by successive visitors to the area. In a large bay enclosed to the west by some islets called Telmo Island on old maps, a kind of shelter on a cliff was found that may have been artificially prepared. Throughout the area and in other large bay, the Media Luna, there was scattered wood debris, seal and sea lion remains, and some whale bones.

In a superficial survey, a skull was found which, according to an anthropological examination conducted at Santiago de Chile University, may correspond to an indigenous woman carried by sea lion hunters as servant in a boat.

Finally, five sites were located with scarce remains of estructures and disseminted materials corresponding to small temporary camps. Excavations in four of them provide the first evidence for the area that matches with similar settlements found in Byers Peninsula, King George Island, and elsewhere in the archipelagos of the South Shetland and Orkney.

The verification of the final process of aboriginal societies of Tierra del Fuego brings up the question of whether it was an isolated case because they were socially and technologically simple societies, or if it was a repeated and general process affecting small scale societies, whose subsistence was centered on hunting, fishing, and gathering.

To check this issue, the processes experienced by other native societies based on fishing-hunting-gathering should be analyzed.

Societies of the Northwest Coast of America

The recurrently considered more complex hunter-gatherer societies inhabited the land at the other end of the American Pacific coast. In the societies on the central coast of North America Northwest, archaeological research show that ethnographic descriptions have important anachronisms, errors, and gaps. Information contrasted archaeologically shows a similar process to Tierra del Fuego: The trigger for the contact was the exploration and fur demand since 1742. Firstly sea otter and then when they were rarefied from 1815, hunters turned to the inland fur trade (mostly for beaver).

Two archaeologists (A. Martindale and P. Prince) both point out a first protohistoric/proto-contact period previous to the nineteenth century in which European influences come indirectly, followed by a second period of exploration and fur trade in the early decades of the nineteenth century. During this time, the indigenous maintain

their economic autonomy and their production relations. After the first settlement of trading posts (Fort Simpson in the Tsimshian area and Fort McLoughlin, further south in the area Bella Colla), there would have been a post-contact phase in which trade and exchange increased until finally shopkeepers, settlers (in 1834, Fort Simpson is founded and in 1849, Fort Rupert), gold seekers (1858), European canneries and sawmills began to settle in the territory and from the second half of the century, eventually swallow the indigenous population in the market society.

Throughout this period, there is a change in relations between Europeans and Indigenous parallel to the process of change experienced by the European society itself (moving from business contact to colonization).

In the coastal Tsimshian area, the first direct contact occurred in 1787. But there is what we call proto-contact period in which, as in Tierra del Fuego, the natives are exposed to indirect influences of Europeans (diseases and European objects like coins and metallic elements, which have been found throughout the Skeena River course). This first European trade's indirect influence is archaeologically perceived besides the presence of some industrial objects, by the increasing number of fur animal remains in the settlements and especially changes in the settlement pattern itself. In the lower Skeena, permanent occupations change to seasonal occupations and new settlements are located, as Metlalka in natural harbors. Inside the lower course of the river, there is a shift to a hierarchy of settlements and larger villages appear along the Skeena and the confluences with tributaries (Exchamsiks and Kitsumkalum).

Another thing was happening in the middle course of the Skeena, in the Gitksan area, where fortified settlements were placed (e.g., sites of Kitwanga-GgTa1-in-Gitlaxdzawk Kitsumkalum Canyon and GdTc1-in Kitselas Canyon) with permanent occupations on the river to participate in the fur trade traffic between the interior and the coast, where European boats arrived. Settlements became more sedentary and large (up to 17 houses), but the houses got smaller and started having European elements.

In brief, there was an increase in the participation of the commercial economy (the subsistence economy losing importance) and a reduction in houses (social segmentation, which could be explained by the effect of diseases but also by the effects of internal segmentation).

The presence of exotic European assets empowers already existing tendencies as e.g., surplus accumulation, violent conflict (the towns became fortified), social inequalities, and the slave trade. The first two are very well documented in the town of Kitwanga Hill Fort dating from the period 1750 to 1859. There, European items are distributed homogeneously in the houses, but at the end of the period, they are more concentrated in certain areas of a central house (Prince 2001). There, fur animal remains are concentrated and exotic goods accumulation is documented as well as a much more varied diet than in the homes of the periphery which are more modest in their construction.

Despite these changes, social reproduction structure remains essentially unchanged in this proto-contact moment. While the size and number of houses in villages are different, the internal structure of the houses will not change substantially until late nineteenth century. Martindale attributes this resistance to change, among other things, to the fact that until the complete settlement of the European colony in Fort Simpson and especially to the final installation of the missionaries, the natives depend on the strategies and traditional subsistence-production relations.

This was documented in the Psacelay site (GbTh-4). In this town, the pre-contact houses are as described ethnographically as large (up to 11 ∗ 18 mm), multifamily, with internal divisions, with an uneven distribution of consumer goods and accumulation of surplus in the "noble" (the innermost) part of the house. In this site, one of the two pre-contact houses is abandoned coinciding with the presence of post-contact European elements in the other house (Martindale 2006); however, the internal structure remains the same. The same happens in the town of Ginakangeek (GbTh-2) where crafted glass, dishes with blue decoration, trapper tools, lead fishing weights, and rifle caskets were found in one of the houses.

Trade of European goods (iron, iron tools, muskets, copper plates, fabrics, paint, sugar, biscuits, molasses, rum, tobacco) was superimposed, taking advantage of preexisting sharing networks (dentaliums, slaves, eulachon oil, dried berries, canoes, etc.) and was used to enhance prestige, with natives as intermediaries and with European ships acting as intermediaries among the natives.

With the installation of Fort Simpson (Port Simpson, British Columbia), from 1834, the natives began to cluster around European settlements, increasingly abandoning their winter settlements. Although hunting and fur preparation was mainly carried out by autonomous indigenous peoples, here, as in Tierra del Fuego, written documents speak about hiring Indigenous labor: first Aleuts by the Russians (1810) and then Indians by the British of Fort Simpson. Furthermore, since 1840, we find the natives integrated to European settlements. From 1870, they become employees in sawmills, packaging plants and they even migrate to the city of Victoria (the settlement of Fort Victoria was installed in 1843).

From the European forts, diseases spread, with one in 1836, killing one third of the native population (Fig. 3).

Similarly in the area of Bella Colla, analysis of all materials at Kimsquit settlements demonstrates a gradual incorporation and modification of European goods which are incorporated into native life, which retains indeed most of its own elements. It is not until the second half of the nineteenth century that the use of these foreign items becomes widespread, albeit sometimes with native functions and uses. That is, European materials were selectively adopted. In some cases, they worked with these materials with traditional techniques, giving them new and original forms different than the ones they had before. However, sometimes, it was not just about replacing traditional items, but that using imported objects acquired added value or that these objects were used as prestige goods (firearms, buttons, uniform, transparent glasses, and keys).

The fur companies that entered from the east of the continent advanced by 1806 to establish forts (Fort St. James, Fort Kilmaurs, and Fort Connelly) in the headwaters of the Pacific. The missionaries of the Church Missionary Society arrived later and settled in 1822 in Red River (Rupert's Land), but in the Pacific Northwest, the first missionary (William Duncan member of the same Church Missionary Society) was installed in Port Simpson much later (in 1857), as in Tierra del Fuego. The objectives and strategies of these missionaries were the same at both ends of the American continent.

Archaeology: The World at 1800–1850, Fig. 3 Historical site Fort Langley. The original was built by the Hudson Bay Company in this place in 1839. Here, in 1858, the colony of British Columbia was proclaimed. The reproduction was built for the touristic visit

Australasia

Although there are different elements, the process that took place in the eastern Pacific had many similarities to the other end of the South Pacific. Archaeology has helped to restore a more complete picture of the early days of European settlement, particularly through the Australian Society for Historical Archaeology founded in 1970 by Judy Birmingham that published a newsletter from 1973. Later, in 1983, this publication became the Australian Journal of Historical Archaeology. This Society from 1991 was extended in Australasian Society for Historical Archaeology that publishes the ASHA Newsletter and Australasian Historical Archaeology Journal, as well as a series of occasional papers and monographs since 1984.

Archaeological works, many published by the Australasian Institute for Maritime Archaeology, have analyzed sunken and stranded shipwrecks and trade of materials transported. Whaling settlements, consumer goods factories (saltworks) and mines, farms, sheep farming, forts, war scenarios, military installations (e.g., the 1840 military settlement of Port Essington or Fort Ligar), prisons, missions, and urban development of cities such as Sydney, Wellington, and Auckland have also been studied. Indigenous life and activities of the subordinate population: Women, and female convicts and aboriginals have been taken into account.

The inrush of the Europeans occurs in an analogous manner: There were some initial Iberian and Dutch seafarers exploratory trips (the archives on the Peninsula are scarcely known and studied by Anglophones scholars), but it was the famous Cook's travels that, in an expansive social context of the metropolis, triggered the scalar increase of the contact. Shortly after his travels, fur seal and sea lion hunting boats started coming to the south coast and southeast, and in 1788, the European settlement in Australia with convicts started in Port Jackson (now part of Sydney). This settlement would be followed by the arrival of the missionaries and little by little, during the first half of the nineteenth century, the interior of the Australian continent was explored.

Although the first to establish seasonal jobs in Van Diemen's Land, present Tasmania, were sealers, the settlement, with soldiers, convicts, and free people, was officially founded in 1803 by a British expedition sent from Sydney to prevent the landing of the French. Colonization was very fast and fatal as evidenced in a punitive expedition of 1815 against the indigenous for killing as many as 930 sheep. The colony quickly became a sheep and livestock colony with hundreds of thousands of cattle, for which they had to take native territories.

The estimated colonial registered population grew from 7185 in 1821 to 24,279 in 1830.

The archaeology in New Zealand, as it is an island and it has similar social and environmental conditions, illustrates the parallels with Tierra del Fuego and the Northwest Coast.

In all of these sites, it can be seen that there was a proto-contact phase (with sailors of various nationalities around their shores) documented by some European items in indigenous contexts: nails, axes, glass, and collar beads. A period of more intense initial contact with seasonal whalers and sealers settlements would follow, which is seen in the increase of these materials in New Zealand (Smith 2005) and the installation of the first penal colonies on the continent. Archaeological research clearly illustrates this contact process in which Aborigines initially tried to take advantage of the presence of Europeans and the introduction of new items incorporating these enclaves within their own networks, which probably like occurred in Tierra del Fuego and in the Northwest Cost, also stimulated significant and stable clusters of people around settlements and European trading points. The settlement of men on the coast generated a certain symbiosis and also problems of isolation and survival of new settlers, transference from the aborigines to the settlers and mixed settlements.

In New Zealand, the first Europeans to settle seasonally were sealers (mostly in the western part of the South Island), in some settlements where, since 1792, they lived with Aboriginal women and their mestizo offsprings. The first official settlement was that of the missionaries of the Church Missionary Society in 1814 in Oihi, Bay of Islands (Middleton 2006).

Colonization was conducted shortly after the system of privileged companies that violated treaties (such as that of Waitangi in 1840) installed more than 20,000 settlers in just 10 years. From 1803 to 1854, there were over 74,000 convicts transported from the British Isles, including some 12,000 women. This expansion policy confined the indigenous, reduced to a quarter, to the most bad lands.

As in the Pacific Northwest (and later in Tierra del Fuego), in the 1850s, the gold rush attracted more settlers to the Australian continent.

Violence and Disease

From the first contact in 1769 between Cook and the Maori in New Zealand, there began the confrontation between Aboriginal and newcomers. In Australia just 4 months after the first settlement in 1788, there was a confrontation. In December 1790, there was the first recognized massacre of indigenous people. On the mainland, the killings continued unpunished until 1838, by military officers, settlers, and ranchers. But it would be extended along the entire nineteenth century (until 1932) as the frontier advanced, and the conflicts would be reproduced between newcomers: between free settlers and deported, and between squatters, ranchers, and farmers.

In Tasmania, although it is assumed that there must have been some previous encounters between Aboriginal peoples and sealers, the first known violent episode occurred the year after the European settlement in 1804. Violence against Aboriginal people did not cease until its peak (the so-called Black War) between 1823 and 1834. After a major "cleansing" operation in the districts already colonized, it culminated in the deportation of all survivors (about 220 people from different groups of Tasmanian) to Wyllbaenna settlement on Flinders Island in Bass Strait. Most would die during capture and confinement: 14 years after their confinement, in 1847, there were only 47 survivors (Birmingham 1992).

This process is quite similar to that which would occur later, with the advance of the sheep border, in Isla Grande of Tierra del Fuego on the Selknam population, which saw them imprisoned in missions, segregated, deported, and confined on Dawson Island.

In New Zealand (after Cook), hostilities were reproduced, this time between sealers and Maori, with the war called the Red Shirt War which lasted from 1809 until the 1820s. As in the Pacific Northwest, with the well-known case of John R. Jewitt from 1802 to 1807 (Jewitt and Stewart 1987), there were Europeans who trespassed over the border to become "Pakeha" Maori. Their knowledge of the habits, ways of acting, production processes, and access to European goods (such as muskets) made them highly appreciated by the natives. This would lead to the creation of a mestizo population segment as the one that had been formed, by 1821, on the islands of Bass Strait in Tasmania.

As in the North American coast, European interference stimulated some preexisting trends in native society. The cultivation of potatoes, as in the Tsimshian area, was quickly adopted and used as an exchange good by the indigenous, allowing them to enjoy lower dependence on subsistence seasonality and increase production and at the same time increase the workforce. This, together with the possibility of acquiring European guns, stimulated and increased preceding tensions, the war and slavery between groups and Maori peoples (as happened also in known cases of the east coast of Vancouver Island). Thus, bloody episodes occurred as in the so-called muskets war among Maori between 1807 and 1842.

The Treaty of Waitangi between the British and Maori, which was signed in 1840, served to turn the archipelago into a colony out of fear of French influence. The Treaty was not respected by the settlers, which resulted in the Maori wars between 1845 and 1872 wars that would definitely change the balance of forces in favor of the newcomers.

As it had occurred in Tierra del Fuego, in regard to armed violence, the kidnapping of natives and their removal to Europe soon followed. In 1790, two Aborigines were taken to show them to the king of England. Women and children abduction was also common in Tasmania occupation (especially between 1816 and 1818).

The first settlements of sealers resulted in the sexual predation on indigenous women for using

them as company for their campaigns between November and May each year. Europeans got them from the natives themselves in Tasmania and New Zealand in exchange for European objects, sealion furs and dogs. Some missionaries were engaged in kidnapping children (especially girls) and they kept them segregated in special enclosures, with the excuse of saving them from venereal disease. As in all the Americas, diseases reduced indigenous populations to a third. The first recorded epidemic occurred around the European settlement in April of the year following their establishment. Epidemics were reproducing regularly in 1792, 1822, 1831, etc. In their explorations, the Europeans continued finding people marked by smallpox, contributing to the suggestion that the diseases were introduced by Asian fishermen from the North before European arrival.

Sexually transmitted diseases, alcoholism, and segregation policy (implemented first by the missionaries and then by the colonial government itself) helped to dismantle the Aboriginal population's reproduction mode, it would take over a century to begin to recover and reorganize it.

Resource Predation

The early days of pinniped exploitation are poorly documented. Records begin in 1791. At the beginning, the aim were the skins (more than 45,000 skins were gathered per year) to be exchanged, first in China for handicrafts, spices, tea, and silks and then in London where oil, fat, and skins were selling well, and where industrial processes of preparation and preservation developed. It affected the regions from the southern shores of Australia to the southern islands of the Antarctic. In the southern coasts of New Zealand, it lasted until mid-1810, but in just 4 years from 1798 to 1802, pinnipeds were overexploited in all the region of the Strait of Tasmania, and the sealer boats had to move increasingly to the South. Business decreased due to hostilities with Maori in the south, with a slight recovery in 1823 after temporary cessation of fighting and the installation of small sedentary settlements. But animal populations in Australia and New Zealand were overkilled in 1830 and the potential for massive exploitations nearly depleted. The exploitation of pinnipeds for their fur and their fat was supplemented in South Australia, Tasmania, and New Zealand and southern islands with intensive exploitation of whales (for their fat, bones, and whalebones) well before 1803. This hunt was conducted from factories located in coves and bays. Depletion of animals near the coast and the competition of the kerosene as fuel by 1850 changed the type of exploitation, directing it to open sea.

In the productive activities of these exploitations, Aboriginal women and some men were incorporated. Aboriginal New Zealanders also participated in this marine exploitation working at the factories situated in the south of the archipelago. Small settlements were formed with a varying mix of natives and Europeans.

Social Dislocation and European Settlement

Missionaries' permanent installation in New Zealand in 1814, the coastal bases of whaling operations, New Zealand forest and linen exploitation, and agropastoral expansion increased these contact and the transferred materials. The rapid colonization of white people led to an advance of the frontiers, increase of armed fighting, and missionary activity. Survivors were relocated and reservations were established, missionaries tried to attract the natives to Christianity, to the European way of life, to resource exploitation of commercial interest and wage labor.

Excavations in the afore mentioned Wybalenna mission in Bass Strait, where Tasmanian natives were relocated between 1833 and 1847, may provide additional light on how Tasmanian Aboriginal society came to disappear. Archaeological work confirms the historians' views, which suggests that the Wybalenna settlement was not viable: Living conditions were the poorest and food was scarce; thus, some Aborigines died from malnutrition and disease. They spent time on hunting local native wildlife to supplement their diet: There is a mixture of bones of small marsupials, molluscs, and European domestic fauna (which will increase its proportion over time). They have also shown that not all residents alike accepted the conditions

imposed: There are knapped glass instruments and different proportions of local and imported animals in the different rooms. It is clear that there was an attempt to reeducate them in the habits (e.g., sweeping the rooms, ceramic tableware) and with the European system (pencils, ink). Other European items, such as buttons, beads, necklace beads, tobacco, and ceramic pipes, should be bought with coins, and thus, the incorporation of natives to the wage labor and market economy is demonstrated. The official establishment of the colonies and the transformation of the settlements into real urban administrative centers since 1840, as well as the establishment of cities such as Sydney (1852), Perth (1856), Melbourne (1847) by Queen Victoria, marks the end of this period of colonial settlement.

The End of Contacted Societies

In all these areas, were native societies subsisted on fishing or hunting, the same process is archaeologically documented, even though it differs qualitatively or is not completely synchronous at a local basis:

1. A proto-contact (indirect or isolated and littoral) whose effects are documented archaeologically by European materials (raw materials and other utensils reformatted with their own techniques and adapted to their own use) found in Aboriginal sites. There was first the impact of European diseases and the gradual adaptation of European technology in a context of social relationships and native subsistence systems. At the same time, a change in settlement patterns to position themselves in relation to this new foreign input, but still within the traditional relations systems, was experienced. Certain existing trends, such as aggregation, women subordination, social inequality, and, in their case, intergroup violence, were stimulated.
2. Direct contact and European settlement (travelers, traders, missionaries, miners, and settlers), which involved new episodes of catastrophic epidemics and sometimes fights/slaughters. These Europeans, after the first contacts that involved more or less violence, tried to kidnap or capture some native people to serve them later as translators or introducers in their society. European settlements that were installed by the mid-century acted as attractors of the indigenous population while spreading diseases, alcoholism and as bridgeheads for waged (independent) labor and bases for exploitation and competition for resources and territory.
3. The integration of natives as a laboring force (guides, trappers, hunters, food suppliers, translators, trade intermediaries) for both men and women, the latter always with the addition of sex, was produced.

Throughout this century, these groups were completely socially unstructured, and even physically almost gone by the first half of the nineteenth century, like the Tasmanians or Beotucos of Newfoundland. The survivors would be integrated into the market economy and even became dependent on it for their livelihood, forming part of the lower salaried classes of the new society.

The long history of these native societies came to a sudden end in the nineteenth century. They could not control the de-structuring effect on their social networks. Although perhaps it provided initially a series of specific daily improvements for a part of these native societies, it was eventually lethal to the survival of their organizational structures. Aboriginal societies would only be "resurrected" or reconstructed as entities, from World War II and for political reasons and following a political struggle.

In this intermission between the first contacts and the disappearances is when religious missions, industrial companies, gold seekers or adventurers, or sailors of marine resource exploitation companies and the different governments that were formed in the new countries that emerged from colonization, played an important role.

Global Causes

So far the description of processes that affected societies at the end of European colonial expansion has been explored. Since the verification of

the existence of this phenomenon and recurring global processes, the evidence reporting the global causes of the end of some social systems that had survived many crises over thousands of years should be analyzed. Allochthonous objects (metal, porcelain, glass, etc.) found in archaeological sites in settlements at the ends of America and Oceania from early nineteenth century came from maritime routes. These items relate to the newly emerging Europe in this century, the nation-state, colonial-expansionist-scientific-industrial-educated Europe.

In the first half of the nineteenth century, Europe was undergoing major changes. European capitalism of the emerging industrial revolution developed and consolidated new sources of energy (steam power machine). Transport systems (such as the train), with coal as fuel and iron as the backbone, widened markedly and there were large movements of people (from the countryside to the cities). All this led to, and was caused by, an increase in the demand for a means of production of increasingly sophisticated, luxury goods for the new upper class/bourgeois society and consumer products for the metropolitan working classes and the new colonial population in expansion. It was about a basically legitimist, clerical, and reactionary Europe, where nationalism and liberalism prevailed. Nationalism was an important political factor and the mercantilist theory provided a stimulus for the development of a new type of colony; the colony was established by Europeans as a social and economic expansion of the metropolis. This system, which required major sources of raw materials and new markets to sell their products, now also started its own colonial expansion. The exploration of last boundaries for evaluating potential resources briefly preceded colonial penetration, which was often justified by cultural and ideological-religious arguments: as a civilizing and/or evangelizing mission.

Therefore, the causes of the disappearance of those native life systems successfully achieved and experienced for so long, with local characteristics and specific crises themselves, were not internal. Commercial competition between nations led to the establishment of new colonies in the new lands, the processes that occurred in the contacts and meetings with the societies called "primitive"/ethnographic led quickly to their end. So their disappearance was caused by a confrontation with a growing external socio-economic system whose intrinsic emerging characteristics made it prevail, destroying those it contacted.

History, after the first contacts, is the history of European colonization.

Transformations in the Colonies

The greed and force of this new system are evident, not only in the new lands that the European metropolis occupied in this century, but in the former colonies established centuries before. The consequences of this struggle between European nations, between the metropolis and its former colonies, or between the new settlers and the Indigenous can be detected archaeologically, along all coasts through archaeological remains of the land and naval battles like the underwater remains of the iconic Trafalgar confrontation.

Rivalries between the major European powers for the appropriation and exploitation of the territories "discovered/conquered" were the first stimulus to scientific-political travels (with adventurers, pillaging, and kidnapping). The voyage of the HMS Beagle is the best-known example of the first half of the nineteenth century (Fig. 4). These trips were aimed at finding and evaluating new resources, exploring possibilities for their exploitation (sealers-whalers-gold-fur-trappers) and establishing new commercial circuits. Goods and circuits are known by archaeological analyses of wrecks and the distribution of allochthonous goods that have been found. From the records of the ships, the circulation of some goods can be followed. Goods that included: porcelain, spices, silk, and tea from China that were exchanged for fine furs of North America or from the Subarctic first, and later opium (in the first Opium War, England imposed its use in 1842); fuel, minerals, wool, cotton, tobacco, groceries, coffee, and sugar in the already established colonies in exchange for value-added products or industrial products (textiles, Staffordshire porcelain, alcoholic beverages, and consumer luxury goods for the ruling classes and the emerging

Archaeology: The World at 1800–1850, Fig. 4 Drawing of Fueguian canoeists made by T. Lanseer and reproduced as engraving in King 1839

middle classes), and of course work force (slave, forced or free, African, European, or Asian).

Under these economic conflicts between European nations, changes of "ownership" of some colonies occurred, for example, the purchase of Florida and Louisiana. Enrichment desires of the new Creole elites – both large producers and urban intermediaries – will lead to the independence of the countries in the early decades of the nineteenth century, processes that were not foreign to the interests of the metropolitan rival powers to get these new markets (such foreign interference had occurred since the first independence, that of the USA). The archaeology of Spanish and French Caribbean colonial fortifications perfectly indicates where the problem came from in the first place.

The idiosyncrasies of the different colonizations are reflected in the particularities of the archaeological evidence and settlement patterns, for example, among the Spanish, French or English Caribbean. The displacements and relocations of settlers also have their archaeological expression when compared archaeologically: for example, the housing structure of the Arcadians compared to the houses of the preinstalled settlers in the south of the United States of America.

The strength of the commercial circuits that were stimulated by the desire of exotic goods and imported products prompted the intensification of production in these ex-colonies, both imported products (coffee) as well as their own products such as rubber, guano, or tobacco. Thus, a new class of landowners, stockholders, and businessmen emerged, who often built a residence in the cities in addition to their large properties and homes in the countryside. As a reflection of what was happening in the metropolis, these emerging new classes in the new countries tried to follow European fashions, imitated behavior styles, architecture, luxury objects, furniture, fashion in clothing, etc. In order to fulfill their needs, they directly imported many luxury items.

The presence of European luxury goods and evidence of new production means is archaeologically confirmed: For example, there was a move from the small artisan press to the sugar mill with the early introduction of the steam engine and the railroad. The set of buildings for sugarcane processing, the sugar mills, have been archaeologically well studied in Cuba, Dominican Republic, Venezuela, and Argentina. In Cuba, for example, at the beginning of the century, sugar mills multiplied, numbering more than a thousand in the 1830s. They produced not only sugar but also began to produce rum. Coffee haciendas in Venezuela, Guatemala, and Cuba have also been archaeologically studied.

Tobacco and cotton were other colonial star products that began to rise in this period. In the USA, large landowner exploitations in the South to small farms in the North have been archaeologically studied. Agricultural intensification explains the flourishing of guano exploitation. In 1845, Peru began exporting this famous fertilizer due to high demand in North America and Europe to increase their agricultural production to cope with population growth.

The same happened with other products to meet industrial demands. For example, the rubber extracted in the subtropical forest was an essential commodity for British industry. There have also been archaeological studies documenting such exploitations.

The same intensification pressed the largest colonies into hinterland occupation where indigenous people survived. They had developed new political, social, and economic organizational strategies, taking advantage of new elements (horses, livestock, crops, weapons).

European expansion, occupation, and the final removal of indigenous people, that have an archaeological reflection at battlefields and military buildings, will start in the first half of the nineteenth century but will intensify and consummate in the second half, from the 1840s.

The most relevant examples of which we have archaeological traces are, in addition to "Maori war," the advance of the whites in South Africa, the "conquest" of the West in the USA, and the so called "war of the desert" in Argentine Patagonia. In Argentina, there was a sustained situation of an unstable border that had generated a native and mixed population which had developed new social and economic strategies: regrouping, mixing, working with cattle and horses, or the exploitation of salt to meet consumption and military demands of the European population, and even participating in the colonial and internal disputes. There is archaeological evidence for the transformation of the natives (e.g., watering hole structures) and Argentine and Spanish ancient forts. The effort to disintegrate the indigenous structure and absorb "undomesticated" – indigenous and gaucho – labor force will be completed with the intensification of the war, and archaeologically well reflected in the forts and border forts and in the means of production and consumer goods recovered at these sites.

The emergence of an urban class of intermediary traders contributed to the remodeling of existing colonial cities and their growth as a service center and as locations for primary processing industries. The case of Buenos Aires is quite illustrative, with a planification that had begun to regulate even before independence in Charles III's regulations (Schávelzon 2002). With the independences, their creole industries, local factories (e.g., china), and at the same time some old ways of organizing work of religious inspiration, such as the Capuchin monks in Venezuela, are terminated (Sanoja 1998).

The same powers (especially Britain), that favored the independence that allowed them to penetrate these markets, stimulated rivalries and interests or divergent plans that emerged between different local elites. Immediately after independence, there followed civil wars and wars between neighbors that tried to prevent the installation of large countries that could threaten the hegemony of the maximum emerging power.

The case of the best-known rivalry and also archaeologically best known was between the USA and Mexico. The expansion of the future new power was oriented not only to the north and west but also southwest, conflicting with Mexico with which they went to war, and they finally snatched 55% of Mexico's former territory.

Economic and Ideological Changes in the Metropolis

Large commercial transatlantic circuits generated a demand for raw materials and at the same time value-added products, which led to the development of mass production that installed a second phase of the industrial revolution, the mechanized factories. This process has been well studied by Industrial Archaeology in central and northern Europe.

The development of urbanization and industrialization on the continent, which had begun in the last third of the previous century, has continued into the first half of the nineteenth century. The demand for labor will attract people from the

countryside to the cities and industrial areas. Industrialization and mass production systems were developed: Fine porcelain production and transfer systems designs are an excellent example well-studied archaeologically. The chain of production processes accelerated the feedback of all these cycles: Textile mills, for example, required the development of new machinery which in turn stimulated metallurgy, the demand for metals and fuels, mining.

This development required a fundamental transformation in production relations. The change meant the end of slavery and the residues of feudal production relations, which were not carried out without resistance. Archaeology has studied the moment of the end of slavery, from the analysis of the remains of sunken slave ships in the Caribbean to the mills and large slave plantations or runaway slave shelters (e.g., in Cuba).

The capitalist mode of production would be based on non-slave wage labor, for which they had to reeducate the workforce. These new production relations had to be imposed by force against the resistance of certain classes of large agricultural producers, but were especially advantageous in industrial environments. Indeed, they had the advantage of reducing fixed costs, labor market flexibility to adapt to the increasing mechanization and massification and generating new cycles of consumption and profit (rental housing, consumer sales that are materialized in industrial colonies whose architectural and archaeological traces are found throughout Europe).

The restructuring of the labor force and economic growth will lead to large population translocations: mass migration of central and northern Europeans toward the colonies, and the displacement of people from India to South Africa. By mid-century, China also began to move toward the Americas. The loss of male labor in the wars between the metropolitan powers in the colonial liberation, in the emigration to the colonies, etc., needed to be replaced: It was therefore about placing women as reproducers (of the labor force and ideology) and also as a reserve labor force.

The political, legal, and economic status of women did not change significantly with the industrial society and liberalism. They continued to be the victims of discrimination. Female labor in factories and mines did become widespread, but in conditions of extreme exploitation and wage discrimination against their male coworkers. Moreover, women were banned from professional areas of greater responsibility and higher education.

Ideological Changes

The existence of labor force and free consumers demanded restructuring relations of social reproduction: the construction of an ideology for alienation and ideological domination on the one hand, and to stimulate the reproduction of the same workforce on the other hand. An ideological shift was essential to achieve a revolution in the reproductive sphere. Linking morals with reproduction has its paradigmatic theorizing in Malthus's work, which, among other things, would serve as a basis for the development of the theory of Evolution and, therefore, the foundation of biology. Parallel changes occurred in political ideology. Nationalism encouraged the identification of consumers with producers unifying and thus favoring domestic consumption in central nations and metropolitan product in the colonies. Colonial elites not only imported luxury items imposing European fashions but a good dose of liberal ideology and a new lifestyle in the image and likeness of the European bourgeoisie.

The cultural demand of these elites is linked to Neoclassicism and Romanticism, which ensures Archaeology of this period is reunited with its own origin. We are in front of the birth of archaeology as a discipline, in parallel to other sciences (such as geology or biology). Nationalism also brought an interest in the past and the role it could play in the construction and legitimation of the present. The remote past – prehistory, and in particular Greco-Roman civilization – becomes the focus of interest and is investigated/excavated. Romanticism, in turn, intensifies the interest for lost civilizations: Near East, Egyptian, Mayan and for a dark common past: Celts and megaliths.

The development of archaeology is linked to the demand for exotic and cultural consumer goods: It is expressed in the architecture

(neo-Gothic, neoclassical) that is documented in the excavations of mansions and gardens that speak for these interests of the bourgeoisie. In the early nineteenth century, the demand for antiques by states and collectors becomes so great that the great museums in Europe and the USA are created to preserve and exhibit relics of the past. Thus, the nineteenth century is the century of the museums, the pillaging of antiquities in Egypt, in Greece (Parthenon friezes are purchased), and exhibition of exotic people – "other peoples" – that reinforce the European system, civilization, and the status quo.

Resistances

However, the enforcement action of this capitalist system immediately provoked significant reactions and social crises. One can speak of the "Europe of revolutions": the bourgeois revolutions and independence revolutions of the colonies which are followed by other crises, revolts, and working class resistances. Unions and social movements emerged as Luddism, opposed mechanization and was severely repressed, Owen's utopian socialism (1839) that inspired the founding of utopian colonies. These culminated in the mid-nineteenth century with the publication of the Communist Manifesto (origin of scientific socialism), the publication of Proudhon's works (origin of anarchism), and the European revolutions of 1848.

In that same year 1848, the first American feminist collective document, the so-called Seneca Falls Declaration, which was approved on 19 July in a Methodist chapel of that locality in the state of New York, became public. This document first expressed what might be called a "feminist philosophy of history." A philosophy which denounces the abuses women had suffered throughout history.

Conclusion

The causes of the disappearance of native social systems based on controlled production and reproduction were structurally and contextually external and violent. Their origin must be sought in Europe and attributed to its initial capitalist system that begins to expand and consolidate in the first half of the nineteenth century. This required a globalization where colonies fructified, soon converted into independent countries, and for its resource and territory voracity implied delimitation of marginalities incompatible with the new system.

Archaeology allows complete our understanding of the global system expansion illuminating the dark side of the story: those elements that were considered not worthy but removable or to be ignored.

Archaeometallurgy of Post-Columbian America

Nicolás C. Ciarlo
Institute of Archaeology, School of Philosophy and Letters, University of Buenos Aires, National Scientific and Technical Research Council (CONICET), Buenos Aires, Argentina

Introduction

Outstanding research has been conducted on ancient metals all over the world within archaeometallurgy. Thus far, this research has addressed a wide range of topics, such as the origins and spread of metallurgy, mining technology, production and circulation of metals, functionality and use of artefacts, and post-depositional deterioration processes. However, archaeometallurgical studies on remains from historical sites (or postmedieval, in Europe) are less frequent. Though written documents, maps, paintings, and photographs, when available, are very useful complementary sources of information for this period, our knowledge of past technologies is not yet sufficiently thorough, as many sites were either poorly documented at the time, or not registered at all. For instance, investigations focused on metal artefacts and other related finds from ca. AD 1500 onward are of special value for their insights into innovations that took place in ferrous metallurgy during the industrialization period (see Bayley et al. 2008, in regard to the case of Britain).

Following the anthropological-sociological theoretical approach to technology proposed by French scholars, from Marcel Mauss to Pierre Lemonnier, metallurgy is here considered as a complex social phenomenon (a technical system) that comprises matter, objects, knowledge, values, gestures (operational sequences), and representations, which both shapes and is shaped by people's meaningful choices and actions. The social dimension of the aforementioned elements is inscribed in their practices and productions. Thus, archaeologists can reconstruct past technical systems through the analysis and interpretation of their material expressions, i.e., the evidence recovered from sites. Moreover, for modern period contexts, field-obtained information is usually combined with data from standing structures, documentary sources, and oral records. Within historical archaeology, intriguing advances have been made in the study of post-contact Native American sites, colonial settlements, battlefields, fortifications, urban and industrial facilities, and shipwrecks.

A brief account of research carried out on metal artefacts from these contexts, mostly developed from the 1990s onward, is offered in this entry. Emphasis is placed on the value of archaeometallurgy for the study of post-Columbian societies in the Americas, both Native American peoples and settlers from European origin. This entry is centered exclusively in archaeology-related topics, focused on aspects of past human lives, and leaving aside advances made in associated areas of study, such as corrosion analysis, conservation, and the authentication of cultural heritage metallic artefacts.

Definition

Archaeometallurgy has been a field of research in its own right for about 50 years. Nowadays, it is widely developed. Investigations carried out in the Near and Middle East, Central and Northern Europe, Mesoamerica and South America, Africa, and China have primarily addressed early metallurgy in those regions up to ca. AD 1500 (see Killick and Fenn 2012; Roberts and

Thornton 2014). Nonetheless, studies within archaeometallurgy are not necessarily circumscribed to a particular period. Available analytical methods and instrumentation crosscut most of the temporal limits that are commonly used in archaeology as a criterion for delimiting areas of research and can be potentially applied to studies covering multiple historical periods and themes. Echoing the words of Rehren and Belford, a separation between an essentially prehistoric approach (mainly based on archaeological remains) and a more historical one (where documentary sources are the primary evidence) is pointless for sites outside Europe. Other than a nominal distinction, the terms *archaeometallurgy* and *historical metallurgy* neither connote any fundamental difference in terms of theoretical and methodological approaches nor regarding research interests and times (Rehren and Belford 2013).

Metallurgical studies conducted within historical archaeology in the Americas as well as in other world regions could be framed within either archaeometallurgy or historical metallurgy. Research developed in these fields cover a wide range of technology-related topics within the modern period both in European countries and overseas: experimentation and improvements in industrial processes, knowledge of ferrous and nonferrous metals, introduction of new materials, development of mass production, endurance of craftsmanship practices, commercial activities and other central-periphery social relationships, and economic and ideological implications of using novel goods in different scenarios, to cite a few. Contributions made so far enable to glimpse the importance of these studies not only for mainstream subjects in historical archaeology but also for discussing invention and innovation processes, technological choices and values, as well as other issues of interest for material culture studies (anthropological archaeology), anthropology of techniques, history of technology and social ideas, and related fields (see Martinón-Torres and Killick 2013, for a discussion on the archaeological science role in the formulation of theory).

Historical Background

The dawn of archaeometallurgy goes back to long before the term was coined. The first metallurgical analysis of antiquities and archaeological remains appeared in the late eighteenth century. For more than a century, metalwork studies were largely devoted to chemical composition determination of iron and copper-based objects such as coins, weapons, and utensils, with the purpose to investigate the materials' quality, manufacturing processes, and their origin. On the other hand, thanks to Henry C. Sorby's contributions to metallographic examination during the 1860s, this technique became a reliable mean to characterize different metal specimens, including archaeological remains. During the twentieth century, mostly in the post-war period, new chemical characterization methods were developed: optical emission spectroscopy (OES), wavelength-dispersive X-ray spectroscopy (WDS), atomic absorption spectroscopy (AAS), and energy-dispersive X-ray fluorescence (EDXRF). Following their application in the laboratory and industry, scientists soon implemented different analyses to determine the composition of large samples of ancient metals, primarily from archaeological sites located in Europe, aiming to identify their provenance (see Rehren and Pernicka 2008). Nonetheless, it was until the 1970s that available analytical means became regularly implemented in truly archaeologically oriented research projects, to answer questions about the life of past human societies. This approach, which strongly depended on the theoretical and methodological development of archaeology, was related with the increasing trustworthy that archaeologists began to show on scientific methods since the previous decade. However, it was not immediately widespread, and ulterior improvements have revealed notorious contrasts between different regions.

Most of the international work on archaeometallurgy is focused on ancient technology, as already mentioned. In the Americas, initial efforts were focused on pre-Columbian metallurgy. Although the interest on this subject traces back to at least the mid-nineteenth century – and even

characterization of prehistoric artefacts were sporadically conducted since then – archaeometric analyses were developed from the mid-1970s onward. Archaeologists dealt with the origins of nonferrous metallurgy and its development by studying the mining, smelting and manufacturing processes, and the usage and circulation of metal artefacts in Native American complex societies. Interdisciplinary projects have been carried out in Argentina, Bolivia, Chile, Colombia, Mexico, Peru, and the USA, among other countries, by both local and foreign researchers. Several investigations on prehistoric metallurgy in the Americas were also conducted by European scholars, among them, from the Institute for Archaeo-Metallurgical Studies (University College London).

Generally, studies have been focused on the characterization of artefacts made of copper, silver, and gold, together with their alloys. Furthermore, they dealt with evidence associated with the metallurgical production process, including waste materials (e.g., minerals and slag), installations, and tools remains (e.g., furnaces, crucibles, and molds). Ethnohistoric and ethnographic research was also combined with data gathered from controlled smelting and casting experiments and from use-wear analysis of metallic instruments. Together, these works have contributed to the understanding of metalworking activities such as the technical knowledge, degree of specialization, scale of production, and functionality of artefacts. Studies performed by leading scholars such as Dorothy Hosler, Luis González, Heather Lechtman, Marcos Martinón-Torres, Izumi Shimada, Thilo Rehren, José Luis Ruvalcaba Sil, David Scott, and co-workers are worth mentioning (see Simmons and Shugar 2013, for a compilation of studies on pre-Hispanic Mesoamerican metallurgy; Cooke et al. 2008, for a brief introduction to ancient metallurgy in Southern South America; and González 2004, for a comprehensive research of this technology in the Argentinean north-western area).

Investigations of metal artefacts within historical archaeology followed a somewhat different course. Since the development of this field in the 1960s, detailed descriptions of morphological and functional features of European manufactures primarily based on a macroscopic examination and documentary sources were conducted. Over time, large typologies used as a reference for technological assessment were developed. Noël Hume's book *A Guide to Artifacts of Colonial America*, first published in 1969, is worth mentioning. It displays several categories of artefacts from the seventeenth and eighteenth centuries, such as buttons and buckles, coins, cutlery and spoons, firearms, and nails, described and illustrated profusely. This work and other akin contributions have been widely used by archaeologists with the aim to identify and perform a first approach to material remains recovered from historical sites. Metals from historic buildings, of interest both to historical archaeologists and art historians, were also subject of detailed cataloging (e.g., Gayle et al. 1992). Moreover, some isolated archaeometric work was carried out with non-archaeological artefacts from museums' collections, chiefly motivated by their historical significance, and following an object-driven approach. In Argentina, a metallurgical examination conducted at the National Energy Atomic Commission allowed authenticating a curved saber located at the National Historical Museum, which most likely belonged to Gen. José de San Martín, who took a leading role in the revolutionary actions against the Spanish rule in Argentina, Chile, and Peru, in the early nineteenth century. This kind of isolated study, even if they may have had certain utility, has usually shown heuristic limitations for archaeological interpretations, due to the lack of artefact contextualization and its limited scope.

Leaving aside a few exceptions, it was necessary to wait until the 1990s for the development of archaeometallurgical analyses of artefacts from historical sites. The development of investigations carried out in Argentina on sites with evidence of European occupation is marked when compared with other Latin American countries. The interdisciplinary work conducted by archaeologists, engineers, and other specialists at the Archaeometallurgy Group (*Grupo de Arqueometalurgia*) of the University of Buenos Aires, under the direction of Horacio De Rosa, should be noted. Over

15 years, several studies were performed on materials from shipwrecks, battlefields, fortlets, and rural and urban sites. Other comparable specialized research groups have been dedicated mostly to pre-Hispanic metallurgy and, in a lesser degree, to post-contact Native American technology. On the other hand, in historical archaeology handbooks and other reference books, there is barely any mention to the potential of metallurgical studies. In addition, several investigations developed in the region are still framed in terms of circumstantial collaborations: archaeologists submit their samples for analysis and then interpret data obtained by specialists who usually do not have a thorough understanding of the archaeological contexts and problems under consideration. This situation, fortunately, is progressively changing towards a closer collaboration between them.

Presented below, is a non-thorough but intriguing selection of works that account for the importance of a truly interdisciplinary approach for current debates in historical archaeology and related fields.

Key Issues/Current Debates

Post-contact Native American Sites

The encounter between Spanish colonizers and Native American people has been a research main topic within historical archaeology. Thus, several post-contact sites were studied for decades. Special interest was placed on the technological changes that this relation triggered, for instance, the adoption of iron utensils, tools, and weapons and its consequences on social practices and ideas. Microstructural and elemental composition analyses offer reliable data to determine the quality of archaeological remains and roughly distinguish the provenance (local vs. foreign) of different artefacts (see Hancock et al. 1991, for a discussion on similarities and differences between Native American copper and European trade cooper). For instance, Wayman and others recorded the metallurgical differences between Arctic native copper samples and nineteenth-century European manufactures made of smelted copper, along with an array of unidentified archaeological artefacts. This study shed light on the use of foreign materials by the Copper Inuit of the west-central Canadian Arctic, in particular the recovery of artefacts from a large cache of provisions abandoned in 1853 by the crew of the HMS *Investigator*, which sunk during an attempt to find the Sir John Franklin's lost expedition (Wayman et al. 1985). Likewise, ulterior works have been centered on identifying exotic materials in post-contact Native American sites, mostly based on the technical characteristics and chemical analysis of the main and trace elements of artefacts. However, only a few have explored the social implications of this widely extended process. The ways in which Native American societies transformed and assigned new meanings to European brass goods in accordance with their metallurgical knowledge and sociocultural worldview were analyzed by Ehrhardt (2005). Also in North America, other authors examined the contact consequences between Spanish and Pueblo inhabitants in colonial New Mexico during the first half of the seventeenth century, in particular related to Pueblo experimentation with metal production using copper and lead local ores, as well as their involvement in the refining of silver and the working and recycling of European copper goods. In this context, as the authors stated, "a complex mosaic of emergent experimentation in novel and hybrid technologies shaped by the requirements of colonial tribute demands, locally available resources, indigenous knowledge and practices, and frontier exchange relationships" was created (Lycett and Thomas 2008: 1651). Indigenous burials have also helped to clarify changes in mortuary patterns and idiosyncrasy after contact. Studies on human remains and the associated material culture in cemeteries show syncretic practices. This is in some cases evidenced by the use of metal artefacts from local and regional provenance, together with European manufactures most likely considered valuable goods, as offerings (e.g., Martinón-Torres et al. 2007). The continuity of traditional metallurgical techniques in colonial and recent times is of special interest to the understanding of Spanish impact on indigenous societies. The ethnographic

and historical work carried out by Rehren and his colleagues in the Poroco-Potosí region, Bolivian Andes, demonstrates that *huayrachinas* (small windblown furnaces) have been used for silver smelting over the last 500 years (e.g., Cohen et al. 2010). How different technological styles were articulated in Northwestern Argentina during colonial times was also discussed by Gluzman and González (2008). Studies conducted by Tapia and her team since the late 1990s on the procurement and use of exotic copper and iron artefacts by different indigenous groups of the Pampa region are also worth mentioning (e.g., Tapia et al. 2009). These cases exemplify how the study of metal remains from post-contact archaeological sites can contribute to anthropological discussions on technology and other social issues.

European Colonial Settlements

Different military, religious, industrial, and other European colonial sites were focus of historical archaeological research. In America, studies on fortified settlements (see below), religious reductions known as missions, mines, and slave villages and plantations, are worth mentioning. Everyday life, defensive strategies, changes in belief systems, labor organization, social differences, and re-signification of artefacts are among the wide repertory of research interests developed so far. Missions of different mendicant orders (e.g., Dominicans, Franciscans, and Jesuits) occupied an outstanding place in the colonial scenario during the seventeenth and eighteenth centuries. At their heyday, these urban centers included churches, schools, cloisters, cemeteries, houses for the indigenous people, and workshops. Several metal artefacts recovered from these installations, such as iron nails and other ironworks, have been analyzed by metallography and chemical analyses. Studies on archaeological remains from these and other historical sites, with focus on material quality and manufacturing processes, were conducted in Argentina by Pifferetti and his colleagues since the late 1990s. Data obtained helped to understand the processes of manufacture and use of ironworks in colonial missions (e.g., Pifferetti et al. 2009). The European exploitation of local mines during the colonial period has been studied by historians, archaeologists, and anthropologists for decades. Archaeometric approaches to the understanding of technical issues on mining, foundry, and metalworking processes have been developed over the last years by some researchers (e.g., Angiorama and Becerra 2017). Works on the production and circulation of silver and gold coins struck both in American and European mints between the sixteenth and eighteenth centuries, made from raw metals of Mesoamerican and South American sources, are of special value for numismatics and related fields (e.g., Le Roy Ladurie et al. 1990; see also investigations of Maria F. Guerra). These and other studies of copper pieces were mainly based on samples from museums' collections, even if metallurgical analyses have also been applied on archaeological coins from more recent times. For the understanding of the extractive activities developed in European colonial settlements, other nonmetallic associated materials, such as fire assay crucibles used for precious metals, were also subject to chemical and mineralogical analysis (e.g., Monette 2013).

Battlefields

Historical battlefields are nowadays one of the main topics within conflict archaeology in the USA. The research conducted during the 1980s on the Battle of the Little Bighorn (1876) was a milestone, and since the 1990s, the path was followed by other studies, first in the USA and later in Latin American countries such as Argentina, Brazil, Colombia, Cuba, and Mexico. These studies have contributed to the knowledge of battlefields' limits, warfare technology, troops' positions, and military tactics, among other issues, thus extending, detailing, and/or criticizing available data from documentary sources. As these brief events have often resulted in unicomponent sites, they are of special interest for the analysis of artefacts used at a very specific moment. On the other hand, since metal detectors are widely used for fieldwork, metal artefacts are common finds, mostly related with armament. Therefore, the technological assessment of artillery (e.g.,

cannons and ammunition), firearms (e.g., flintlock muskets, percussion smoothbores, breech-loading rifles, round balls and bullets, and casings), bladed weapons (e.g., sabers and knives), and also uniforms' accessories, mostly from nineteenth-century sites, has been well developed within this field. Data recovered from metallurgical analyses can help archaeologists to identify the remains belonging to different contenders, for instance, the ammunition used by the Federal and Confederate armies in American Civil War battles (Caporaso et al. 2008). Quality and provenance of iron for rifle barrels manufactured at the Springfield Armory at that time were also evaluated through metallurgical analyses of arms and contemporary iron from the Marshall's works in England (Gordon 1983). Works of this kind aided as well to the knowledge of industrial ferrous metallurgy in the USA (see below). On the other hand, evidence recovered from frontier warfare contexts is of special interest for studies on technological change, such as the process of modernization and standardization of the Argentinean army's armament during the second half of the nineteenth century (Leoni 2014). In addition, combining a morphometric approach with characterization analyses, technical specifications of different types of arms were determined. Extensive archaeometallurgical work with different artefacts from battlefields and other military sites has been carried out so far by some scholars (see Landa 2011). Nonetheless, and despite the potential of these studies for discussing technological issues, most research on metal remains is still based solely on typological classifications.

Fortifications and Other Installations

A wide range of permanent or temporary military sites at inland and coastal locations have been studied within historical archaeology. Along with battlefields, they constitute a remarkable data source for archaeological interpretations on past conflict. Different types of European fortified settlements are distributed across the continent, being South American sites worth to mention. Del Cairo Hurtado studied a Spanish coastal defense system at Cartagena de Indias, Colombia, focusing on the siege of the city by the British fleet under the command of Vice Admiral Edward Vernon in 1741 (e.g., del Cairo Hurtado 2011). Eighteenth-century forts and batteries that the Iberian Crowns established in Brazil and Uruguay to protect their territories were also studied by historians and archaeologists, Marcos Albuquerque among them, who examined their architectural characteristics and the settlers' daily practices. In Argentina, archaeological research has focused on several nineteenth-century forts and fortlets established in the Pampa region as part of the Buenos Aires government strategy to occupy and preserve the vast territory inhabited by Native American groups. As for material culture concerns, the weapons used at these fortifications have also been a central topic of study. Furthermore, new insight into the people who occupied these places was obtained by the analyses of uniform accessories, cooking utensils, tools, and other elements used in daily life. Procurement, use, reuse, and discard of artefacts within these sites, and their social implications for commissioned troops, are as well among the main subjects developed heretofore. Analyses of materials from the *Fortín* Otamendi (Buenos Aires, 1858–1869), *Fortín* Miñana (Buenos Aires, 1860–1863), and *Fortín* La Perra (La Pampa, 1883–1885) are also noteworthy (e.g., Tapia et al. 2007; Landa et al. 2009). Other artefacts recovered from different fortifications throughout America were also subject to characterization studies since the 2000s.

Urban Contexts and Industrial Facilities

Different central and peripheral urban areas and industrial facilities from the late eighteenth century onward were studied by archaeologists. Households, public buildings, factories and workshops, churches, cemeteries, detention centers, harbor structures, garbage dumps, and so on have been excavated. A plethora of materials related to diverse activities was recovered from these sites. And as well as in the earlier colonial establishments mentioned, metal remains are pervasive at these scenarios. Even if studies conducted so far on findings are mainly based on a

morphometric approach, specialists have also applied the available analytical means for their technological assessment. Gordon (1991) discussed technical issues related to the American crucible steelmaking process, introduced from England during early 1860s. The various uses of industrial iron and steel products also were considered by a few scholars. The contribution of Elban and Goodway (2004) to knowledge of the technology of wire cables used for mid-nineteenth-century girders in the USA can be highlighted. Despite the undoubted significance of these and other investigations for industrial and engineering history, they are mostly focused on specific features of isolated artefacts and usually neglect their value for the discussion of major archaeological problems. Interdisciplinary and diachronic studies such as that conducted by Unglik (1990) at the ironworks of Saint-Maurice, Quebec, are still scarce. Artefacts recovered from this place by Canadian Parks Service were mostly produced in a charcoal blast furnace using high-phosphorus iron ores and show different microstructures: gray, white, and mottled cast iron. Structure and composition variability of analyzed materials were associated with four occupational periods of the site, thus contributing to understand the technological changes developed there between 1667 and 1883. Research developed at a site belonging to the once San José de Flores settlement, nowadays a district of the City of Buenos Aires, is also worth to mention. There, evidence of thermoalteration was recognized in over 90% of a sample of iron artefacts recovered. This, along with the study of nonmetallic remains, allowed archaeologists to demonstrate that this place was a dumpster where garbage was burnt until the early twentieth century (Frustaci et al. 2011). It is also worth to mention recent works developed by Carlos Landa and his team on a rural village of about 500 inhabitants and on several posts of the Pampa region. The archaeometallurgical studies of a wide variety of remains from these sites supplied information about utensils, tools, and weapons used by the first people who settled in the region at the beginning of the twentieth century.

Shipwrecks

Watercraft technology associated with both Native American maritime and riverine activities, and European sailing to and from the Americas territories, has been addressed by maritime and nautical archaeologists. Archaeological researches on historical sites have been conducted by North American scholars since the late 1960s, mainly in Canada and the USA, while investigations in southern countries begs to be developed about 25 years later. Metallic elements found at wooden shipwrecks were subjected to different physical and chemical analyses since early 2000s. Remains of iron- and steel-hulled ships have not been dealt with until very recently, with the exception of the comprehensive investigation and preservation developed by Paul Mardikian and other conservation scientists on the hull of the American Civil War submarine *H.L. Hunley*, 1864 (e.g., González-Pereyra et al. 2010). Analyses conducted by Jones on the copper sheathing and tacks recovered from the Mica shipwreck, a nineteenth-century deepwater site located in the Gulf of Mexico, as well as on samples from other shipwrecks of the period, are also worth mentioning (Jones 2004). Further studies were performed on other historical sites, but they focused on very punctual samples and were merely descriptive. Within Latin America, extensive work has been done in Argentina. Metal artefacts recovered from the British sloop-of-war HMS *Swift* (1770), lost off Puerto Deseado, Santa Cruz, and from a late eighteenth-century Spanish merchant ship located in the city of Buenos Aires were studied during several years. Furthermore, several specific studies were done in other sites from the seventeenth to twentieth centuries (see Ciarlo 2015, for an account of these investigations). Moreover, much work has been carried out in this country with metal samples from shipwrecks located in Spain, such as the French warships *Fougueux* (1805) and *Bucentaure* (1805), the Spanish warships *Triunfante* (1795), and a British transport known as Deltebre I (1813) site (e.g., Ciarlo 2016). In recent years, analyses of this kind were introduced for the study of historical shipwrecks in Chile and Mexico, but there are still few published reports. These studies

have been performed on pieces such as hull fastenings and sheathing plates, to determine the manufacturing processes and materials' composition. In occasions, for which usable data on industrial patents and other documentary sources were available, the results obtained served as supplementary information to date and assess the provenance of the remains.

Future Directions

Metal remains are nearly ubiquitous in historical sites, and the potential for their study is clearly reflected in the results attained so far. These remains have proven valuable for our understanding of post-Columbian Native American and European societies. To predict the future of archaeometallurgical studies is, nonetheless, a risky endeavor. Archaeometallurgical studies on historical sites show a heterogeneous development nowadays, so no evident trend can be recognized. While considerable research has been conducted in certain sites, with emphasis on specific topics and materials, there is still a noticeable void in numerous others. As Pollard and Bray (2007) pointed out for archaeometry, strengthening existing interdisciplinary links and creating new ones on the basis of a genuine communication, shared objectives, and mutual academic respect will certainly be helpful for further developments in this field. The isolation of researchers, within and beyond archaeology, has resulted in nothing but theoretical-methodological stagnancy and misinterpretations. Both synthesizing data – not only from several sites but of different kinds of material evidence, also – and deepening discussions grounded on anthropological and sociological theory are fruitful paths to improve our understanding of metallurgy and the role it played in post-Colombian societies. This will certainly depend on whether scholars decide to embrace a still more essential approach: in archaeometallurgy, characterization analyses and interpretation of data should seek from the very start to answer archaeological questions. Ultimately, the latter will rely on the efficient integration of specialists throughout the whole research process. Current prospects include a wide compass of exciting research subjects, ranging from the ways of procurement and creative uses of foreign technologies by Native American peoples to the characteristics of blacksmith workshops and the emergence of local iron and steel industries. Even if the first steps have already been taken in this direction, archaeometallurgical studies on historical sites in the Americas should certainly be further explored.

Archaeometry Laboratory at the University of Missouri Research Reactor (MURR)

Michael D. Glascock
Archaeometry Laboratory, University of Missouri, Columbia, MO, USA

Basic Information

The Archaeometry Laboratory at the University of Missouri Research Reactor (MURR) supports collaborative research on archaeological materials to answer questions about past human behavior (http://archaeometry.missouri.edu). Using information from trace-element and/or isotopic characterization of artifacts, raw materials, and human remains, the Archaeometry Lab at MURR works

with archaeologists to investigate resource utilization, trade and exchange, human migration, and environmental adaptation. The laboratory was established in 1988 with support from the National Science Foundation and the University of Missouri (Glascock et al. 2007).

Major Impact

The well-equipped Archaeometry Lab is one of the few laboratories in the world dedicated to performing this type of research and is unique for having these powerful analytical methods under one roof. The main analytical capabilities available in the Archaeometry Lab at MURR include:

- Neutron activation analysis (NAA) – The 10 MW Research Reactor is the largest university-owned research reactor in the world. MURR has the highest possible sensitivities for NAA, especially useful for bulk analysis of pottery, obsidian and other artifact types requiring minimal sample preparation.
- X-ray fluorescence (XRF) – Table top and portable XRF spectrometers enable nondestructive surface analysis of materials such as obsidian, metals, glazes, and paints.
- Inductively coupled plasma-mass spectrometry (ICP-MS) – Three spectrometers (i.e., quadrupole, high-resolution, and multi-collector) and associated equipment (i.e., laser ablation and microwave) provide the highest possible sensitivities by ICP-MS for trace elements and isotope ratios in a wide variety of artifact types.
- Petrography – A petrographic microscope enables the identification of minerals present in thin-sections of ceramic materials.

Laboratory personnel are highly trained and have several years of experience in collaborating on compositional analysis with the archaeological community. Laboratory personnel include the following professional scientists:

- Dr. Michael D. Glascock (Ph.D., 1975, Iowa State University) is a Research Professor and the Group Leader of the Archaeometry Lab with more than 35 years of experience with NAA and gamma-ray spectroscopy as applied to archaeology, geochemistry and environmental science. His research focus is on obsidian source and artifact characterization in Mesoamerica, South America, and the Russian Far East.
- Dr. Jeffery R. Ferguson (Ph.D., 2007, University of Colorado) is a Research Assistant Professor in the Archaeometry Lab. His research focus is on the archaeology of western and southwestern North America.
- Mr. Matthew T. Boulanger (M.A., 2009, University of Missouri; current Ph.D. candidate) is a Research Specialist in the Archaeometry Lab. His research focus is on the archaeology of eastern North America, landscape ecology, and geographic information systems applied to archaeology.

The Archaeometry Lab's scientists are supported by several skilled technicians most of whom are undergraduates at the University of Missouri. The student technicians perform sample preparation, collect analytical data, and archival of artifacts. They are also frequently involved in various aspects of data interpretation and report writing as part of their educational and research experience. The experiences gained by the undergraduate students who work for the Archaeometry Lab make them well prepared to perform graduate research in archaeology in the future.

The laboratory encourages short-term visits by graduate students and faculty from other universities who are collaborating with the Archaeometry Lab. The laboratory provides training in the preparation of artifacts for chemical analysis, offers recommendations regarding the selection of appropriate samples, gives guidance in selecting the appropriate trace-element and isotopic methods, and provides instruction in the application of multivariate statistical methods for data interpretation.

Customized software developed by the Archaeometry Lab for interpretation of

compositional data on artifacts and source materials is available. The Archaeometry Lab software performs many of the multivariate statistical operations commonly employed to interpret large multivariate datasets, including principal components analysis, canonical discriminant analysis, cluster analysis, Euclidean distance calculations, Mahalanobis distance calculations, missing value replacement, bivariate and trivariate plotting, and compositional profile plots. The software is distributed from the Archaeometry Lab webpages at no cost to the user.

Since 1988, the Archaeometry Laboratory at MURR has collaborated on hundreds of research projects ranging in size from one sample to 2,000 samples. The total database of analyzed archaeological samples numbers more than 110,000 specimens. Approximately 70% of the samples are ceramics and clays; 25% are obsidian artifacts and source specimens; and the remaining 5% are chert, basalt, limestone, metals, etc. The database enables many collections of artifacts, both small and large, to be traced to specific locations around the world. In recent years, more than compositional data 6,000 samples per year have been added to the compositional database. These data are continually added to our website and are available for download after publication by the principal investigator.

Archaeometry: Definition

E. Christian Wells
Department of Anthropology, University of South Florida, Tampa, FL, USA

Brief Definition of the Topic

Archaeometry (*syn*. archaeological science) is a formal field of study whose practitioners apply techniques and approaches from the physical, material, chemical, biological, and Earth sciences and engineering to address archaeological questions and problems. Together, the sciences provide archaeology with empirical and systematic ways of collecting, analyzing, synthesizing, and interpreting data related to the inorganic and organic material record of human history. Investigations involve both instrumental and non-instrumental approaches and target materials research (e.g., properties of substances and their constituents) as well as chemical and biological substances and residues, from the molecular scale all the way up to macroscopically observable artifacts and ecofacts. Applications of archaeometry take place in field, lab, and museum settings and include a wide array of topics, such as radiocarbon dating, provenance of ceramics, stone tool production and use, properties of metals, diet and health in ancient populations, geophysical prospection, soil chemical residues, computer and statistical modeling, and the conservation of archaeological objects and historical monuments. Archaeometric techniques are fundamentally important to archaeological research, because they reveal the varied ways in which humans engage the material world and the range of Earth processes that are involved in this relationship – from the production, use, and modification of natural and synthetic materials to their ultimate deposition in the archaeological record, the cultural and natural processes that impact them until they are recovered by archaeologists, and their long-term care and conservation.

In the early 1950s, Christopher Hawkes at Oxford coined the term *archaeometry* to

characterize the growing emphasis of absolute dating, physicochemical analysis, and quantification in archaeology. By the late 1950s, an international journal, *Archaeometry*, was established, followed in 1961 by the first annual scientific meetings of the International Symposium on Archaeometry. That same year, Martin Aiken (1961) and Karl Butzer (1964) produced some of the first textbooks on the subject. In the 1970s, archaeometric research accelerated around the world, with an important textbook by Michael Tite (1972); a new international journal in 1974, *Journal of Archaeological Science*; and the creation of the Society for Archaeological Sciences in 1977. Today, the field is as vibrant as ever, with occasional edited volumes in the long-standing *Archaeological Chemistry* series from the American Chemical Society (since 1974) and the *Materials Issues in Art and Archaeology* series from the Materials Research Society (since 1988), many new textbooks (e.g., Brothwell and Pollard 2001; Edwards and Vandenabeele 2012; Goldberg and Macphail 2006; Larsen 2015; Malainey 2011; Pollard and Heron 2008; Price and Burton 2012; Rice 2015; Stuart 2007), and three new journals, *Journal of Archaeological Science: Reports*, *Archaeological and Anthropological Sciences*, and *STAR: Science and Technology of Archaeological Research*.

Introduction

Parasites are a major cause of morbidity and mortality in the world today. Parasites are organisms that live in or on other organisms called hosts, obtaining sustenance and shelter from their hosts to carry out reproduction in host tissues and structures. Taxonomic diversity characterizes parasites, and they include a wide range of organisms ranging from single-celled protozoa to arthropods such as fleas. There are two general types of parasites: ectoparasites such as lice and endoparasites such as intestinal worms. The maladies provoked by parasites include malaria, elephantiasis, kala-azar, sleeping sickness, river blindness, dysentery, crabs, and guinea worm disease. These diseases, some commonplace and some exotic, were and are significant threats, especially for peoples whose social complexity did not include effective sanitation, hygiene, and germ theory awareness.

Past infection patterns were defined by human behaviors and environmental conditions. Archaeoparasitology explores these relationships. Researchers depend on archaeological data concerning subsistence, medicines, community size, water sources, social complexity, environment, trade patterns, and many other lines of archaeological investigation. Researchers are also familiar with principles of parasite ecology as applied to complex parasite life cycles. The archaeological questions that can be addressed are varied in scope. The longest application has been to broad based study of the large-scale cultural developments on infection and disease. There has been long-term interest in how the transition to agriculture, development of complex societies, and the evolution of empires affected parasitism. These issues were address by population studies of many sites across long periods of time. On the most restricted scale, archaeoparasitological analysis applied to a single burial or mummy can show infection intensity and medicinal response to symptoms of infection (Reinhard and Araújo 2012).

The success of the methods relates to the fecundity of parasites. Parasites produce thousands of larvae, cysts, or eggs. In archaeological contexts, even when the structures of cysts and eggs fully decompose, antigens and DNA can be diagnosed in the lab. Thus, archaeoparasitology is methodologically diverse. It is common now to see molecular biology (aDNA analysis), immunology (ELISA), louse quantification, and quantification of worm burden presented in the literature. Through this multidisciplinary approach, all types of parasites can be found. Gross pathology, as seen in mummies and skeletons, is another source of data.

Archaeoparasitologists use a diversity of concepts and theories in their work. The basic archaeological principles of association, context, features, dating, and stratigraphy. For any given region, reliance on archaeological assessment of cultural development, subsistence, and technology is needed. A wealth of theoretical perspectives has been generated by parasitology. The combination of parasitological theory and archaeological principles/assessments can be used to generate testable hypotheses. This emerging area is called pathoecology (Martinson et al. 2003; Reinhard and Araújo 2012). This review details some of these developments.

Pathoecology assesses infection risk based on an analysis of species of parasites diagnosed in a specific region and time. The health risk of infection is assessed with a knowledge of nutrition and behavior. The focus of pathoecology is on discovery of where parasite transmission took place. Field archaeology has a goal of identifying specific behavior features in sites and regions.

Archaeoparasitologists assess the infection potential of features that were conducive for parasite transmission. From the parasitological perspective, the nidus concept can to be applied to assessing transmission potential of features (Reinhard and Araújo 2012; Reinhard and Bryant 2008; Slepchenko and Reinhard 2018). Yevgeny Pavlovsky was a Russian parasitologist who developed the model of any given parasite infection being dependent on the overlap of parasite and host in a geographical space that favors transmission (Slepchenko and Reinhard 2018). The nidus is this space. From the archaeoparasitological perspective, this space can be as finite as a kissing bug infested room feature that enclosed dog and human susceptible hosts. Within this nidus, the nocturnal kissing bugs were the transmission vector for the parasite *Trypanosoma cruzi* which can cause American sleeping sickness, also Chagas disease. The sleeping dogs and humans became infected by the feeding of the bugs. In contrast, the nidus can be much larger. In prehistoric and historic times, people in Peru experienced susceptibility to leishmaniasis, a disfiguring disease that affects the nasal mucosa (Martinson et al. 2003). The *Leishmania* protozoa were transferred by sandfly vectors. The weak-flying sandflies are active at dusk in still-air environments such as forests and are active around animal burrows. Therefore, the nidus for infection can be as large as a forest in which people were carrying out late day activities. Several parasites were normally infecting the same population. Because the life cycles of the parasites are known, the overlapping nidi of several parasites can be deduced. Therefore, the nidi and risk behaviors of the populations can be inferred and compared as shown for Andean peoples and ancestral Pueblos (Reinhard and Araújo 2012; Reinhard and Bryant 2008). Thus, pathoecology is based on application of the nidus concept and can explain infection patterns for remote times and places.

Parasite pathoecology can be applied at very large scales to explore parasite patterns between continents. This has been done to understand differences in fecal-born parasitism, also called filth-borne infection. Decades of research has shown that filth-borne parasitism was extraordinarily common in Europe, from the origins of agriculture onward. Paradoxically, these parasites were well controlled in the prehistoric Americas. Archaeologically, the most common filth borne parasites are evinced by the long-lasting eggs of *Ascaris lumbricoides* and *Trichuris trichiura*. Reinhard and Pucu (2014) defined these patterns and explained the behaviors behind this contrast. Behaviors in Europe promoted infection. These included use of feces as fertilizer, unconfined disposal of excrement, poor personal hygiene, and crowding. Therefore, Europeans established nidi for transmission in water sources, gardens, streets, and other localities. It is likely that the humoral concept, the basis of European medicine, exacerbated the problem by failure to recognized contagion as an infection source. Prehistoric American populations had a number of behaviors that reduced exposure to filth. Population centers were less crowded than Europe. Many anthelminthic medical therapies were known. Sanitation systems restricted fecal contamination. There may have been a perception of infection causality. Agricultural practices limited pathogen transmission. Therefore, nidi for filth borne transmission were not established in American prehistoric societies. High fiber diet led to spontaneous clearance of worm infections (Reinhard and Pucu 2014). Therefore, from finite spaces in archaeological sites to large-scale comparisons, the nidus concept and pathoecology are very useful in understanding different trajectories of parasite-human associations.

Another large region with a unique history of parasitism is central Russia (Slepchenko and Reinhard 2018). Russia, the home of Yevgeny Pavlovsky who innovated the nidus concept, has a long history of parasitological investigation of archaeological sites. Burials and mummies are the foci of analysis (Figs. 1 and 2). Unlike the Europe, and similar to the prehistoric Americas, filth-borne worm infections were rare among central and western Russian indigenous people. Instead, people in this region were infected by parasites transmitted by consumption of animal products. In a parallel way, their dogs were also infected with fish borne parasites. Indeed, the first

Archaeoparasitology, Fig. 1 A partial mummy analyzed from the Doge-Bary II burial ground were carried out in 1990–1998 by the Central-Asian expedition led by K.V. Chugunov. This is the only Russian mummy which was positive for whipworm eggs. The arrow indicates the area sampled (Slavinsky et al. 2018)

Archaeoparasitology, Fig. 2 A burial sampled from at Neftprovod II was excavated and sampled. (**a**) The location where the sediment sample was collected for the paleoparasitological analysis; (**b**) the location where the control soil sample was collected; (**c**) the arrow indicates the direction of north

archaeoparasitological studies in the region focused on dog coprolites. This evidence dated to the Neolithic and Mesolithic of the area of Moscow. The sites belong to Lyalovskaya and Verkhnevolzhskaya archaeological cultures. The samples revealed eggs of the tapeworms *Diphyllobothrium* sp., *Spirometra* sp., the nematodes *Dioctophyme renale,* Capillariidae*,* and the flukes *Alaria alata*, and *Opisthorchis felineus* (Slepchenko and Reinhard 2018). Of these parasites, the *Diphyllobothrium* fish tapeworm and the fluke *Opisthorchis felineus* infect humans. These cases result in the passage of eggs by human hosts. Pathology is caused by *O. felineus* in humans when it invades the biliary and pancreatic ducts. *Spirometra* sp. and *Dioctophyme renale* cause disease in humans. In the case of *Spirometra* sp., the parasite larvae migrate under the skin of humans forming nodules. A more severe disease, sparganosis, occurs if the larvae migrate to the brain or eyes. The kidney worm *D. renal* in humans occurs when the worms migrate to a kidney and reduces that kidney's function. Infections involved just one kidney, but the symptoms of infection can be severe or even fatal. From other parts of Russia, *O. felineus* in dog coprolites were diagnosed. These were from the Bronze and Iron Age site of Maray I in the forest-steppe zone of Western Siberia and the Yarte VI of the lower Yuribey river, Yamal Peninsula. *Strongyloides papillosus* was also found in Maray I. The seventeenth-century period of the Siberian Arctic city, Mangazeya, was analyzed with foci on dog coprolites and organic sediments. The parasites *O. felineus, Diphyllobothrium latum*, *Toxocara canis*, and *Fasciola hepatica* were found in the samples. The sheep liver fluke, *F. hepatica*, infects both dogs and humans. Dogs are the normal host for *T. canis*. When larvae of this parasite hatch from their eggs in the human intestine, they migrate from the intestine to surrounding tissue and even the spinal cord and eye. Therefore, subsistence based on incompletely cooked fish, and association with dogs and their parasites, defined the pathoecology of this city. A series of analyses of burial grounds in western Siberia confirm human infection with parasites transmitted by eating fish. These include the cemeteries of Zeleny Yar, Kikki-Akki, Vesakoyaha II, Vesakoyaha IV, and Nyamboyto I (Slepchenko and Reinhard 2018). The sites date from as early as the twelfth century to as late as the nineteenth century. *Diphyllobothrium latum* and *O. felineus* were the most common parasites discovered. Interestingly,

Archaeoparasitology, Fig. 3 A pelvis sample from the Bronze Age Neftprovod II burial ground in East Siberia revealed the presence of *Taenia* sp. eggs. This showed that the individual likely consumed raw or undercooked meat of roe deer, red deer, or elk infected with *Taenia*

eggs consistent with the beef tapeworm, *Taenia saginata*, were found in the Vesakoyaha VI and Vesakoyaha VII burial grounds (Fig. 3). Ethnographic and experimental studies indicate that people could have become infected by eating reindeer brain. The existing data from this large region of Russia show a unique pattern of infection resulting from dog association and eating incompletely cooked fish and meat.

Archaeological parasitology focuses primarily on the diagnosis of parasites from data sources such as latrines, coprolites, mummies, and other organic contexts. Especially in the Americas, coprolites and mummies provided epidemiological data sources for analysis of parasite distributions. It is a goal of archaeoparasitology to develop sufficiently extensive and compelling data sets to present true epidemiological pictures of ancient human-parasite interactions. A large base of persuasive evidence will reveal the parasite-human ecology of ancient people who had very different lives than any modern peoples. To accomplish this, archaeoparasitologists must demonstrate that parasitological patterns typical of modern host populations can be discerned through extensive archaeological study. An axiom in parasitology is that a minority of hosts carries the majority of parasites. This is known as the negative binomial distribution. Once methods were developed to quantify the relative number of parasites represented in any given sample, then the presence or absence of the negative binomial can be assessed. Several studies of both ectoparasites and endoparasites showed that the negative binomial is evident in archaeological series (Camacho et al. 2018). The strongest of these is the analysis of coprolites from La Cueva de los Muertos Chiquitos, Rio Zape, Durango, Mexico (Morrow and Reinhard 2017). This analysis of 100 coprolites dating between 1200 and 1400 years old revealed an ancient endemic health challenge from the most ubiquitous worm parasite of humans, pinworm. Egg per gram of sample values demonstrated an overdispersed pattern of distribution among the samples (66% uninfected, 25% less than 100 eggs/g, 8% between 100–500 eggs/g, and 1% over 500 eggs/g). In this analysis, 10% of the samples contained the vast majority of parasite eggs. The demonstration of negative binomial distribution in archaeology is of crucial importance because archaeoparasitology has equivalent epidemiological strength as modern surveys of living populations. The negative binomial was previously shown for lice in ancient Peruvians (Reinhard and Buikstra 2003). The infection quantification of large archaeological populations is becoming a revolution in archaeological parasitology.

With large sample sizes, temporal and social parameters of infection can be discerned. The parasitological analysis of latrine features can provide the best evidence of parasite emergence and control related to sanitation. Trigg and her colleagues (2017) combined data amassed from New England historic sites by several researchers between 1986 and 2007. The data included analysis of 114 latrine features from seven cities dating between AD 1650 and 1900. The key methodological feature of this analysis is that all researchers used the same quantification technique to calculate the number of parasite eggs per milliliter of latrine sediment. Also, the authors focused on the most durable eggs produced by the filth-borne parasites, *A. lumbricoides* and *T. trichiura*. Because historic archaeologists

often have direct documentation as to the status, occupation, and even names of families who used latrines, socioeconomic information can be overlaid on the archaeoparasitological data. Using this extensive data set, the authors defined biological and cultural variables that shaped the pathoecology of developing cities. Control of these parasites was gradually achieved, beginning with *T. trichiura* and eventually with both parasites by the end of the nineteenth century. Environmental and behavioral factors affected this change. This included changing microenvironments linked to urbanization, innovation of sanitation, and reduced use of urban spaces for fecal disposal. Initially, poorer households were infected due use of feces-contaminated yard spaces for food gardens. Also the poor had a delayed access to sanitation. This study reflects the progress of archaeoparasitology in historic archaeology, a field that can provide extensive samples with known and documented cultural information.

Investigation of the range and genetic configuration of parasites across time and large geographic ranges provides insight into evolution of parasites after host switching events. Such studies have modified our understanding of the ancient origins of today's parasitic diseases. For example, decades of research into the origins of Chagas disease and *T. cruzi* involving all types of analysis changed our perception and knowledge based regarding this protozoan parasite as reviewed by Reinhard and Araùjo (2014). Through most of the twentieth century, parasitologists thought that *T. cruzi* first arose to infect human in the Andes when animals were domesticated, and agricultural villages developed. Guinea pigs and dogs are and were alternative hosts. Accordingly, when dogs, humans, and guinea pigs began to live in kissing bug-infested domiciles, then infection became common in humans. This process was called domiciliation. It was a surprise when, in 2003, evidence of infection predating animal domestication was discovered. Also, discoveries of infection were made well outside of the Andean geographic range. Molecular biology became an important tool in diagnosing infection in mummies. When DNA diagnosis was achieved for a large series of mummies, an exciting and detail history of *T. cruzi* in the Andes was published. Among hunter-gatherers, there was a host switch to humans on the part of *T. cruzi* some 9,000 years ago. Infection persisted until colonial times in. In later papers, molecular biologists were able to test for the six variants of *T. cruzi* DNA. It was shown that the oldest infections were with wild strains of *T. cruzi* and probably were provoked by oral ingestion of contaminated food. Three domiciled strains infected Andean populations after agriculture and animal domestication. More recently, the analysis of *T. cruzi* DNA strains in modern populations raised another question. Molecular biologists identified a unique *T. cruzi* DNA, TcIDOM. This variant causes a significant proportion of South American human infections. However, it is a wild strain in North/Central America. The researchers who made this discovery proposed a new hypothesis. They hypothesized that TcIDOM had an origin in North America in paleo times. It was spread into South America by ancient migrations. In the process, it became domiciled. They acknowledged some problems with this hypothesis; (1) hunter-gatherer population densities were not large enough to support a continuous domestic cycle and (2) early populations were inherently unsuitable for the transmission of TcIDOM genotype because the populations were small and dynamic. Reinhard and Araújo (2014) addressed this hypothesis by reviewing the archaeology of the Lower Pecos Canyonlands in Texas and Coahuila. The archaeology of this regions shows that the Archaic population was large and sedentary enough to maintain transmission at least by 5000 years ago. In this region, earth oven cooking technology altered the landscape and boosted the wild infection cycle between rodents and kissing bugs. Hunting the wild rodent hosts of *T. cruzi* resulted in kissing bugs infesting human sleeping areas. Therefore, *T. cruzi* potentially underwent a *defacto* domiciliation among Archaic peoples in North America. The lessons learned from decades of archaeoparasitology focused on *T. cruzi* entirely transformed the scientific understanding of the origins of Chagas disease. The original Andean domiciliation was too simplistic. Intense

molecular scrutiny brought to light a more multifaceted web of host switching events involving six parasite strains over two continents and alternate transmission through kissing bug feeding and also oral ingestion of infective agents.

On a more basic level, simple archaeological documentation of time and location of infection benefits the understanding of emergent diseases. Viral and bacterial emergent diseases are widely sensationalized today. However, archaeoparasitology shows that parasites emerged and reemerged throughout time. Kuchta and his colleagues (2015) described the health challenge of Pacific broad tapeworm infection, *Adenocephalus pacificus* through 6,000 years of prehistory in context of modern infection patterns. This parasite normally infects sea lions. The final intermediate hosts, several species of fish, are and were eaten by dogs and humans. As a result, dogs and humans become infected in Peru and Chile as evidenced by mummies. In Archaic periods, infection prevalence fluctuated with climate conditions (Kuchta et al. 2016). Infection was variable after agriculture. Therefore, human and environmental conditions resulted in emergence, disappearance, and reemergence of infection.

The data reviewed thus far are based on the recovery and identification of microscopic eggs and larvae or molecular signals of the specific parasites. Gross pathology exhibited in skeletal remains provides additional evidence of parasitism. Some somatic infections result in calcifications recoverable in cemetery excavations. Working on cemeteries from a Medieval Icelandic hospital, Kristjánsdóttir and Collins (2010) recovered evidence of hydatid cyst disease and presented several cases. *Echinococcus granulosus*, a tapeworm, provokes hydatid cyst disease in humans. The liver and lungs are the most commonly affected, but cysts can form in other tissues as well. Large cysts form which may contain daughter cysts. The cysts can remain asymptomatic for months or years, and the cyst grows slowly and can take a decade to become 15–20 cm in diameter. The cysts calcify and form resistant structures that weather taphonomic processes that destroy soft tissue. Therefore, they can be found in skeleton context. The cyst calcification relates to its complex structure. The outer layer is composed of modified host cells that form a dense fibrous protection around the cyst. The middle layer is laminated without cellular structure. The inner layer is the germinal layer where larval tapeworms are produced. These larval forms accumulate within the cyst. Calcification is a result of host tissue reaction to the hydatid cyst that essentially walls off the cyst (Waters-Rist et al. 2014). Densely calcified inactive cysts are resilient evidence of infection when found in cemetery context (Kristjánsdóttir and Collins 2010).

Wild carnivores and ungulates are the usual hosts of *E. granulosus* (Waters-Rist et al. 2014). In Iceland, by medieval times, the parasite cycled between dogs and sheep. Sheep were the intermediate hosts infected with cysts. Dogs were the definitive host infected with egg-laying adult worms. The eggs were passed into the human environment in dog feces. The eggs, once fortuitously ingested by humans, formed hydatid cysts. Kristjánsdóttir and Collins (2011) note that hydatidosis was a prevalent endemic health problem in Iceland. The disease became the focus of a strict control campaign by the late 1800s. The AD 1493–1554 monastic hospital cemetery shows how severe the problem was in the evidence of hydatid cysts recovered in skeletal context. The eight cases were buried in close association to each other, suggesting that hydatidosis was a recognized syndrome by the monks. The largest hydatid cyst known from archaeological context was recovered from this hospital cemetery. All infected individuals were 50 years and the cysts were equally divided between men and women. Calcification of hydatid cysts was attained in 5% of 160 individuals excavated from the cemeteries. Only 20–30% of hydatid cysts calcify. Therefore, the percentage of the population infected could have been as high as 25%. This study shows how careful excavation of a large population can offer understanding of the creation of a prolonged cycle involving dogs and sheep that resulted human infection and disease (Kristjánsdóttir and Collins 2011).

The study of parasite decomposition, or taphonomy, is a new area of study. Certain parasites, such as *A. lumbricoides* and *T. trichiura*, lay durable eggs designed to stay infective for years. Eggs of such parasites preserve in archaeological contexts very well (Rácz et al. 2015). Other parasites such as hookworm have infective larvae that hatch out of the eggs shortly after entering the extracorporeal environment. These eggs and larvae preserve very poorly. Other parasites, such as pinworm, lay light eggs for airborne dissemination. These eggs preserve only in the optimal environments provided by coprolites and mummies. Various taphonomic conditions differentially affect preservation of parasites species (Morrow et al. 2016). Human remains from the same cemeteries show an absence of parasites with skeletonized burials and ubiquitous parasites in mummified burials (Seo et al. 2010).

Recognizing this difference, Korean researchers focused their work on mummies, making extraordinary discoveries concerning past distribution of parasite infections (Seo et al. 2014) (Fig. 4). The Korean researchers combine microscopic and molecular diagnoses. Fascinating work has based on mummies from Joseon Dynasty tombs fifteenth to nineteenth century. Seo and his colleagues diagnosed four species of food-borne helminths. All of these are trematodes, or flukes. Flukes are parasitic flatworms and in these studies, two species infected humans by fish or crab consumptions. The fish-borne flukes include *Clonorchis sinensis* (Chinese liver fluke) and *Metagonimus yokogawai*, an intestinal fluke. One-third of the mummies were infected with one or both of these flukes, five with *C. sinensis* and three with *M. yokogawai*. These analyses show that uncooked fish was commonly eaten by the people of Joseon society. Eating uncooked crab was the infection source of the lung fluke, *Paragonimus westermani* which was found in about one third of the mummies. Oysters were the source of the intestinal fluke, *Gymnophalloides seoi*, infecting about one eighteenth of the mummies (Fig. 4). In total, 11 of 18 Joseon mummies were infected with one or more species of fluke. Filth-borne parasites nematode worm parasites were also found (Fig. 5). When the nematode data are added to the picture, all 18 mummies were positive for one or more species. Ten mummies contained eggs of *A. lumbricoides* and 13 were positive for *T. trichiura*. Therefore, fecal pollution of the human environment was a problem (Fig. 6–7). Pinworm has an airborne and person-to-person infection transmission cycle. Pinworm eggs were found in two mummies which infection within habitations. A rare parasite, *Strongyloides stercoralis*, was discovered in a mummy. Infection occurs when larvae of these parasites burrow

Archaeoparasitology, Fig. 4 Coprolites remained inside the large intestine cavity of Korean mummy

Archaeoparasitology, Fig. 5 *Gymnophalloides* seoi egg discovered in Korean mummy coprolite sample. People became infected by eating oysters, the intermediate host of this intestinal fluke. One in eighteen mummies, on average, were infected

through the skin. Another rare parasite, *Trichostrongylus*, was found. The larvae of this genus must be eaten to transmit infection. These last two parasites were found together in a single mummy. The pathoecology reflected by these 18 mummies is complex. The nidi of infection included the water sources from which fish, oysters, and crabs were gathered (flukes), the fields in which plants were harvested (*Trichostrongylus*), fecal contaminated cities (*A. lumbricoides* and *T. trichiura*), and even the enclosed structures in which the elite lived (pinworm).

Archaeoparasitology, Fig. 6 Scanning electron microscopic image of *Trichuris trichiura* from Korean mummy (Yangju). The infection was due to fecal contamination of the environment

Reinhard (1992), in a foundation article, anticipated that parasitology would become a tool for the archaeologist. Specifically, he expected that parasite data would reveal details of diet, transhumance, trade, environmental contaminants, health, interaction with domestic animals, and human-parasite ecology and evolution. Today we see the maturation of archaeoparasitology as it has made contributions in all of these areas. However, as molecular biology continued to be refined as a diagnostic tool, the field made strides towards showing evolution of parasites through time and geographical space. From this perspective, archaeology is now contributing to parasitological theory of how parasites switch from animal hosts to humans and then persist and spread with humans. When human behavior developed in a way that promoted infection, then parasites

Archaeoparasitology, Fig. 7 Archaeoparasitological study showed that the archaeological strata of Old Seoul City containing many soil-transmitted parasite eggs, showing the possibility of fecal contamination of the human environment during dynastic period of Korea. Therefore, fecal contamination of the human environment was a problem since infection can be associated with unwashed food

became part of the enduring archaeological landscape.

Archaic *Homo sapiens*

Xinzhi Wu
Department of Palaeoanthropology, Institute of Vertebrate Palaeontology and Palaeoanthropology, Chinese Academy of Sciences, Beijing, China

Introduction

In Asia and Africa, many human fossils of Middle and early Late Pleistocene age cannot be allocated to *Homo erectus* (sensu lato), premodern and anatomically modern *Homo sapiens*. They are generally allocated in a taxon, referred to as early or archaic *Homo sapiens*. But recently, a growing number of paleoanthropologists prefer to attribute some of them to other taxons such as *Homo heidelbergensis* or *Homo rhodesiensis*. Specimens of this kind, such as that from Kabwe and Bodo, will not be included in this entry. In the following section, fossils that are usually included in the taxon archaic *Homo sapiens* from Asia and Africa will be described.

Key Issues/Current Debates/Future Directions/Examples

Dali

The site is situated at a loess terrace in Dali County, northwestern China. The human fossil is a rather complete cranium, but the lower part of the face was deformed by the upward depression of the alveolar process. It is associated with Mode I lithics and mammalian fossils of late Middle Pleistocene age. U-series (^{231}Pa/^{230}Th) dating of an ox tooth, associated with the human cranium, gave an age of 209 ± 23 ka. The stratum of human skull is 13 m below a layer of paleosol which is estimated as around 247 ka with IRSL analysis, so the human fossil is earlier than this age; ^{230}Th analysis of the enamel and dentine of an associated rhinoceros gave ages of 258 + 34/−26 ka and 349 + 53/−38 ka, respectively; ESR analysis of the associated Lamprotula resulted in an age range of 297 to ~210 ka. All of these suggest a date of between 300 and 260 ka. The ESR/U-series date for animal teeth is around 281 ka.

The human cranium is rather robust and has many metrical features intermediate between *Homo erectus* and modern humans and shows a morphological mosaic between these categories. Some measurements and indices of Dali fall within the range of modern humans, whereas some features seem to be in the status intermediate between Middle Pleistocene hominins of eastern and western Eurasia. The cranial wall and brow ridges are as thick as that of the hominin from Locality 1 of Zhoukoudian. The brow ridge is thickest at its middle part. The most protruding point of the median sagittal profile of the frontal bone is located at its lower half. The cranial capacity is 1,120 cc. There is no supraorbital notch, foramen, and tubercle. In addition, it has many features similar to that of Jinniushan cranium. These are as follows: a median sagittal ridge at the lower part of the frontal squama; the fronto-nasal and fronto-maxillary sutures form a curve which is nearly horizontal but slightly convex upward; an angular torus; the superior border of the temporal squama is slightly curved; the notch between the squamosal and mastoid portions of the temporal is rather deep; the mastoid process is small; between occipital and nuchal planes there is an angular turn marked by a weak occipital torus which extends along the middle two-thirds of the occipital squama; the zygomatic arch is thin, and its upper border is slightly lower than the Frankfurt horizontal; the nasal profile is nearly vertical; the infero-lateral orbital margin is blunt and forms a nearly right angle; the anterolateral surface of the fronto-sphenoidal process of zygomatic bone faces more forward and the lower margin of the zygomatic process of the maxilla is curved.

Jinniushan

The site is a cave located on Jinniushan Hill, Yingkou Municipality, northeastern China. Human fossils include a nearly complete, but broken, human cranium, 6 vertebrae, 2 ribs, 1 left ulna, 9 carpal bones, 2 metacarpals, 7 digits of a hand, 1 left innominate, 1 patella, 11 tarsals, 2 metatarsals, and 13 digital bones of the foot. They are associated with Mode I lithics and a lot of mammalian fossils of Middle Pleistocene age. A U-series date on associated animal teeth is around 280 ka. The cranial capacity is 1,390 cc. The cranial wall is close to that of modern humans in thickness. Brow ridge is not thick, and its thickest point is at the medial part, while the thinnest is in the middle. The postorbital constriction is obvious. There is a supraorbital notch, and the supraorbital process is distinct. The nasal bones are wide. The upper incisors are shovel-shaped. The coronoid process of the ulna resembles that of modern humans in shape. The position of iliac buttress is more anterior than that in modern humans. This structure and the ischial tuberosity are gracile.

Xujiayao

The site is located on the west bank of the Liyigou River, 1 km southwest of Xujiayao Village, Yanggao County, North China. Human fossils include 12 parietal fragments, 2 fragments of occipital, a nearly complete temporal bone, lower part of a child maxilla with teeth, a mandibular fragment, and several teeth. The fossils were embedded in lacustrine deposits also associated

with Mode I lithics and mammalian fossils of early Late Pleistocene age. U-series dates on associated rhinoceros range between 125 and 104 ka.

Parietal No. 6 is rather complete, with distinct parietal tuberosity. It is slightly smaller and much thinner than Parietal No. 10 which is intact except for its anterior part. The branches of the middle meningeal artery are thinner than that in *Homo erectus* from Zhoukoudian but thicker and less ramified than that in modern humans. The supero-posterior corner of both parietals is naturally lacking, hinting at the possible existence of an Inca bone. Other parietal fragments are small. The Parietals Nos. 3 and 4 are similar to No. 6 in the presence of straight grooves on the outer surface. These grooves radiate forward, upward, and backward from the parietal tuberosity and seem to represent traces of scraping before death. The bregmatic region of Parietal No. 5 is full of dense small foramina that are probably due to osteoporosis or represent cribra cranii externa. No. 10 is a pair of partial posteromedial parietal bones from an adult. It exhibits a congenital defect, an enlarged parietal foramen. The posterior part of Parietal No. 14 has a small hole that seems to represent a healed wound. The thickness of most parts of the parietals is within the range of variation of *Homo erectus* from Zhoukoudian. Both occipital fragments (Nos. 7 and 15) are very thick. The cerebral fossa is larger and deeper than the cerebellar fossa in Occipital No. 7. A shallow supratoral sulcus exists on Occipital No. 15 but not on No. 7. The temporal bone is of left side. The mastoid process is small and the muscular markings on the surface of the temporal squama are strong. The thickness at the parietomastoid suture behind the parietal notch and at the occipitomastoid suture medial to the mastoid process is very close to the range of that in *Homo erectus* from Zhoukoudian. The length-height index of the temporal squama is 64.5. The tympanic plate is more medially located than that in *Homo erectus* from Zhoukoudian and Hexian. The thickness of the tympanic plate is intermediate between *Homo erectus* from Zhoukoudian and modern humans. The styloid process and stylomastoid foramen align with the mastoid notch. The transverse section of the pyramid is closer to *Homo erectus* from Zhoukoudian than to modern humans, but the upper border of the pyramid is as sharp as that in modern humans. The anterior nasal spine is distinct but not prominent. Five teeth are attached to the left maxilla. A newly erupted median incisor is shovel-shaped. The canine and molar have strong cingulum but the isolated left upper molar has no cingulum. All teeth are larger than that of female *Homo erectus* from Zhoukoudian, some measurements are even larger than the male from the latter.

Maba

The site is said to be situated in a cave on Shizishan Hill, 1.5 km southwest of Maba Village, Shaoguan Municipality, southern China. The human fossil is a skull-cap which was unearthed by local farmers. The mammalian fauna from the same cave provides a U-series date of between 135 and 128 ka. No stone artifacts were found.

A short median ridge exists on the frontal squama above the supraorbital groove, which is rather deep except for its median part. The frontal tubercle is weakly developed. The middle and lateral segments of the brow ridge are 11 and 12 mm thick, respectively. A top view of the skull shows the medial end of the brow ridge is located more anteriorly than the lateral end. There is a trace of the fusion of the metopic suture on the anterior surface of the glabellar region. The post-orbital constriction is as exaggerated as that of *Homo erectus* from Zhoukoudian. The frontal sinus is rather large. A semilunar scar 14 mm long exists on the outer surface posterolateral to the right frontal tubercle. On the inner cranial surface at the place roughly corresponding to this scar, there is a bulging about the same size. The parietal is 7.0 mm thick at both the bregmatic region and parietal tuberosity. The fronto-nasal and fronto-maxillary sutures form a more or less horizontal curve. The naso-malar angle is 146°. A median longitudinal narrow ridge exists on the nasal bones, the profile of which is close to a right angle. Most of the right orbit is preserved and is more or less spherical. Its infero-lateral margin is sharp instead of blunt. The orbital index is 88.0. There is no supraorbital notch, foramen, and

tubercle. The anterolateral surface of the right fronto-sphenoidal process of the zygomatic bone faces more forward.

Chaoxian

The site is situated at Yinshan Hill, Chaoxian County, eastern China. Fragments of occipital and maxilla, as well as three isolated teeth, were found from deposit of a limestone fissure, associated with mammalian fauna of Middle Pleistocene age. No artifacts were found. U-series date of associated animal teeth is between 200 and 160 ka.

The occipital torus consists of two curved eminences that are short and only slightly prominent. The transition between the occipital and nuchal planes is rounded. No external protuberance exists. The supratoral sulcus is indistinct, except for a small fovea seemingly corresponding to the suprainiac fossa. Distance between inion and endinion is 22.0 mm, and the thickness at the center of the occipital torus is 7.0 mm. The pyriform orifice is probably rather wide. The incisive canal extends more or less vertically. The massiveness of the teeth is within the range of *Homo erectus* of China. Attrition of anterior teeth (only the lateral incisors are preserved) is much greater than that of the molars. It has been suggested that this difference may imply that the anterior teeth functioned as tools for chewing hard and tough food.

Changyang

The site is in Longdong Cave, Changyang County, Central China. The lower part of a maxilla was found by local farmers, and an isolated left lower second premolar was found by Lanpo Jia from the same cave. No artifacts were found. U-series date of presumably associated mammalian teeth is around 195 ka. The straight line connecting the nasospinale and prosthion forms a 60° angle with a plane deduced from the occlusal surface of the first premolar and first molar attached on the maxilla. The massiveness of the premolar and molar is close to the lower limit and median value of *Homo erectus* of China, respectively.

Dingcun

The site is at the gravel on the third terrace along the east bank of the Fenhe River near Dingcun Village, Xiangfen County, North China. Human fossils include three teeth of a child and a fragment of infantile parietal bone. They are associated with Mode I lithics and mammalian fauna of Late Pleistocene age. U-series date of associated mammalian teeth is between 210 and 160 ka. Lamprotula fossils yielded a U-series date of 150–83 ka. Both upper median and lateral incisors are shovel-shaped with weak basal tubercles and fewer finger-like processes. All of these teeth are much smaller than the corresponding teeth of *Homo erectus*. The shape of the supero-posterior corner of the parietal indicates the possibility of the presence of an Inca bone.

Miaohoushan

The site is at a limestone quarry at Miaohoushan Hill, in Benxi Municipality, northeastern China. Two human teeth and a fragment of femur were found in association with mammalian fauna, with a U-series date of between 240 and 140 ka. The human upper canine is much smaller than that of *Homo erectus* from Zhoukoudian, and the lower molar is close to the lower limit of the latter.

Tongzi

The site is at Yanhuidong Cave, Tongzi County, southwestern China. Human fossils include five teeth. They are associated with Mode I lithics and mammalian fossils of Late Pleistocene age. U-series dated to between 180 and 110 ka. The upper median incisor is shovel-shaped, with three finger-like processes. The canine has a basal tubercle and cingulum. The left premolar has traces of cingulum. Cingulum is obvious and very weak in the left and right molars, respectively. The size of most of the teeth is within the range of *Homo erectus* from Zhoukoudian, except the canine and the left molar, the breadths of which are slightly shorter.

Dadong

The site is at Dadong Cave, Panxian County, southwestern China. Human fossils include two teeth. They are associated with Mode I lithics and

mammalian fossils of Late Middle Pleistocene age. The upper median incisor is shovel-shaped. The canine has a cingulum. The root of the canine shrinks suddenly near its tip. These teeth are slightly smaller than that of *Homo erectus* from Zhoukoudian.

Locality 4 of Zhoukoudian

An upper first premolar was found in association with mammalian fauna of Middle Pleistocene age and Mode I stone artifacts. Thermoluminescence dates for the associated ash layer is 257 ka. The size of this human premolar is within the range of *Homo erectus* but without cingulum.

Narmada

The right half of a human skull was found on the surface of an alluvial terrace along the Narmada River, 200 m west of Hathnora Village, central India. Stone artifacts and vertebrate fossils have been found from the sandy/silty boulder conglomerate in the area where the Narmada cranium was found. Based on the mammalian fossils, the Narmada cranium is inferred to be of late Middle Pleistocene age. The Narmada cranium is moderately large and long. Cranial capacity is estimated as 1,200 ml. The frontal is not very receding, and the vault is high and narrow. Its broadest part is across the enlarged mound-like supramastoid ridge. The temporal squama is very long but not very high. The parietal notch is vertical and bears an ossicle. The postorbital constriction is moderately shallow. The supraorbital torus is strongly arched and uniformly thick across. The orbital roof is moderately concave.

Zuttiyeh (Galilee)

The frontal bone with part of a left zygomatic was found in a cave on the edge of the Wadi Amud, below the Amud site, and about 3.5 km from the Sea of Galilee. The associated lithics are generally considered as pre-Mousterian from the Acheulean-Yabrudian industry, and an age of well over 200 ka has been suggested. The arched supraorbital torus of both sides connects across the glabella. The lateral portion of the torus is thinner. The forehead rises quite sharply behind a narrow supratoral groove. Five or six lesions are shown on the frontal. The interorbital region is wide. The anterior part of the zygomatic arch sweeps back, curving laterally very rapidly. Demarcation between the temporal and infratemporal fossae is very clear.

Jebel Irhoud

The human remains include a broken, but fairly complete, cranium, a skull-cap, a broken juvenile mandible, and a juvenile humerus. They were apparently unearthed near the bottom of a fissure in limestone near Chemaia, about 60 km east of Safi, Morocco. A precise provenance is recorded only for the humerus. Fauna from the deposit suggests an early Late Pleistocene age. ESR date estimates on three teeth found just above the humerus range from 90 to 125 ka. The site has yielded a Levalloiso-Mousterian lithic industry. The human crania are inferred to date to between 130 and 190 ka. These human fossils have been suggested to have Neanderthal affinities and are described as morphologically archaic, although foreshadowing modern humans. Cranial capacity of Jebel Irhoud I is 1,305 ml.

Salé

The base and rear of a braincase plus a partial left maxilla and a natural endocranial cast were found by quarry workers from dune deposits ~1.5 km from the coast at el-Hamra, Douar Caid bel Aroussi, Morocco. A 400 ka date seems plausible based on the local geological context. There are no associated archaeological deposits. The human skull is fairly small and tall with a capacity of 880 ml. It is broadest across the supramastoid regions which are slightly swollen. The temporal line is quite high and arches up slightly. The temporal squama is very short, but for its length it is quite high. The styloid process is thin. A rather large stylomastoid foramen lies between the styloid process and the base of the mastoid process. A hind view shows the cranial wall to be short and quite vertical. The transition from occipital to nuchal plane is rounded. The cranial bone is thick. Pathological thickening of the midsection of the frontal extends back over the bregma. The first and second upper molars apparently have

thick post-cingulum running down the side of the metacone to the small hypocone region.

Singa

The calvaria were found in calcrete deposits exposed on the west bank of the Blue Nile, some 46 km downstream from Singa, and ~320 km south of Khartoum, eastern Sudan. An early Late Pleistocene date was inferred based on the fauna recovered at Singa. U-Th dating of the calcrete adherent to the cranium gave a result indicating the minimum date for the fossil to be 133 ± 2 ka. The human calvaria might even have been associated with the final Acheulean. The human skull is relatively long and moderately high, with a short frontal rise that is fairly steep. The broadest part of the skull is across the parietal eminences. The temporal squama is relatively long and not very high. The parietomastoid suture is long and horizontal, and the parietal notch is very shallow and open. The mastoid process is very small, thin, and short. The supramastoid crest is distinct. The wall of the left auditory meatus is pathologically thickened. The temporal fossa is undifferentiated from the infratemporal fossa. A top view shows the supraorbital margin to be relatively straight, retreating moderately from the glabellar region; postorbital constriction is fairly strong. In general, the cranial bone is thin, except for thickening in the region of the externally, quite swollen, parietal tuberosities. Cranial capacity is estimated at 1,550–1,600 ml. The supraorbital tori are not very thick. The orbital roof is shallow.

Ndutu

The partial adult cranium was found from the lake margin sediments along western side of Lake Ndutu, at western end of Olduvai Gorge, northern Tanzania. The date is probably in the order of 400 ka or about 200 ka based on correlation with different volcanic tuffs in the region. Handaxes have been found at the site that were almost certainly from the same horizon as the human cranium. Reconstruction shows the braincase is small, short, broad, and quite low. Cranial capacity is 1,100 ml. The transition from occipital to nuchal planes is rounded. A hind view of the vault is almost square in outline. The broadest point would have been across the supramastoid crest. Diploe is thick, inner and outer tables are quite thin. The preserved left supraorbital torus is moderately thick. The posttoral surface is slightly depressed. The temporal squama is relatively long, probably arched and high. The mastoid processes are very stout. The supramastoid crests are moderate. The parietomastoid suture is relatively long and horizontal. There is a large wormian bone at the lambda region. Cerebellar fossae are larger and shallower than the cerebral fossae. The interorbital region would have been quite broad. On the left side, the anterior root of the zygomatic arch originates rather low, not too far above the alveolar margin. It appears that the anterior extent of the zygomatic arch faces more or less forward. Both left premolars have two distinct roots that probably bifurcated close to the neck.

Florisbad

The human fossils were found from spring deposit about 45 km northwest of Bloemfontein, South Africa. The sedimentary sequence consists of "peat" layers. Human and animal fossils were found at the level of lowest peat layer, Peat 1, for which U-series date is over 100 ka. In all levels below Peat 3, general Middle Stone Age artifacts have been reported. The partial calvaria are high and rounded. The frontal recedes somewhat directly from the supraorbital margin, with only a hint of a supratoral plane. The temporal line is low. A top view shows the glabellar region protrudes forward. The supraorbital margin is quite thick in the medial portion and thinner in the lateral portion. There is something of a break centrally between the medial and lateral portions of the torus. The orbital roof is very shallow and concave. The infero-lateral corner of the orbit is not sharply defined. The interorbital region is moderately wide. The cranial bone is thick with very thick diploe and extensive porotic hyperostosis, as well as large number of healed lesions, including pathological drainage or vascular tracts. A couple of large puncture marks and some scratch-like marks may reflect carnivore activity. The partial facial bone shows that the inferior margin of the anterior root of the zygomatic arch oriented forward and directly out sideways. The

third cranial fragment also has thick inner and outer tables and diploe.

Guomde

The cranial fragments were found on the surface of the Guomde Formation southeast of Ileret, on the northern sector of the east shore of Lake Turkana, northern Kenya. No archaeological findings have been reported for this site. The specimen KNM-ER 3884 represents the rear of a skull reconstructed from many individual pieces, plus a reconstructed maxilla with all the teeth, and the anterior part of a frontal. The cranial capacity is estimated to be 1,400 ml. The supraorbital tori are double arched and uniformly thick from side to side. There is no distinct supratoral sulcus or plane. Postorbital constriction is minimal. Stylomastoid foramen lies close to the base of a thin styloid process on the left side but far lateral to it on right side. The mastoid process is relatively thin. Canine fossa is not identifiable.

Eliye Springs (West Turkana)

The human cranium is a surface found near the freshwater Eliye Springs, on the southwestern shore of Lake Turkana, Kenya. No artifacts have been found. The neurocranium is large and high, with a cranial volume of more than 1,300 cc. In side view, the frontal rises fairly steep, the transition between the occipital and nuchal planes is somewhat angular. The temporal line is an obviously high curve. The temporal squama is rather long and very high. The demarcation between the temporal and infratemporal fossae is quite clear. The parietal notch is fairly deep and narrow. Postorbital constriction is weak. The frontal sinus is very large. The interorbital region is extremely wide. The nasal bones are broad. The left orbital roof is shallow. The nasal cavity is relatively small.

Ngaloba

The human fossils consist of a fairly complete calvaria with a maxilla and part of the nasal region. They were found on the surface of the Serengeti Plains of northern Tanzania, about 40 km south of Olduvai Gorge. U-series analyses on bone indicate the age ranging between 129 and 108 ka. A Middle Stone Age assemblage has been found from the Ngaloba Beds, both in situ and on the surface. The vault is narrow, with a long frontal. The supraorbital tori are thick, without a posttoral groove. The postorbital constriction is very weak. The transition from the occipital to the nuchal planes is rounded. The occipital plane appears "bunned" because the nuchal plane undercuts it strongly. There is neither a clearly defined occipital torus nor a well-defined external occipital protuberance. A posterior view shows the braincase forms a smoothly rounded curve. A small circular depression on the left parietal near the lambdoid suture is probably of pathological origin. The temporal squama is quite high, and the upper border is quite arched. The temporal and infratemporal fossae are separated by an angle in the alisphenoid. The tympanic plate is very thick. There is a supramastoid swelling instead of a crest. The mastoid process is medial-laterally narrow and not very projecting. The styloid process is relatively thick and is situated medially and in front of the large stylomastoid foramen. The cranial capacity was estimated to be 1,367 cc. The vault bone is quite thick, especially around the midline and in the occipital region. The interorbital region is quite broad. The nasoalveolar clivus is straight, moderate in length and angles slightly out and down. The junction between the maxillary body and the zygomatic process of the maxilla is fairly high above the alveolar margin. The lower border of the zygomatic process forms a sharp angle with the maxillary body. The right P1-M1 and left M1-M3 are preserved, none were very large.

Lake Eyasi

A partial cranium and other cranial fragments were found on the surface at an open-air site on the northeastern shore of Lake Eyasi, near Mumba Hill, northern Tanzania. They are believed to be of late Middle Pleistocene or early Late Pleistocene age. The archaeological context is uncertain. It may be of a terminal Middle Stone Age, or earliest Middle Stone Age. The skull is long and low with large brow ridges. The occipital is very thick, angle between nuchal and occipital planes is

quite obtuse. The angle between the occipital and nuchal planes is quite obtuse. The left cerebral fossa is large and deep, whereas the left cerebellar fossa is not as deep as the cerebral fossa. A larger mandibular fragment has a moderately deep symphyseal profile, in which the anterior surface angles back to the inferior margin, producing a low bulge. There are traces of a low keel above the bulge. A slight depression exists under the root of the lateral incisor. The thickest part of the symphysis is quite far above the inferior margin. The genial pit is shallow and broad. Small mental foramen lies quite high up below septum between two premolars. A much smaller mandibular fragment is confined to the symphyseal region. A low broad keel descends from the region below two median incisors, quickly broadens into a very wide triangular elevation, that becomes very salient closer to the inferior margin. Shallow depressions lie on either side of the keel. The postincisal plane is vertical. The thickest part of the symphysis is close to the inferior margin. Digastric fossae are very small.

Saldanha

The calvaria and fragment of mandibular ramus were found on the surface some 24 km east of Saldana Bay, Northern Cape, South Africa. The fauna from the same general area is said to be of early Middle Pleistocene age. Stone artifacts said to be of Late Acheulean have been found from the same general area. The braincase is large, long, and low. The widest part is in the supramastoid region. The cranial capacity is 1,225 ml. The squamosal suture may have been shallowly curved for most of its length. The occipital and nuchal planes form an angle. Along the junction of these planes, the bone bulges in a distinct horizontal torus with a small groove above and undercutting below. The cranial bone is moderately thick. The postorbital constriction is distinct but not exaggerated. The brow ridges curve strongly and smoothly back from the midline. The ridge is very thick especially at the middle of the orbits. The orbital roof is shallowly concave. The interorbital region is quite broad.

Despite the fact that archaic *Homo sapiens* has been considered a meaningless taxon by some paleoanthropologists, it has been a useful one in dealing with human evolution. As shown in the above descriptions, it has a rather broad diversity in morphology which exhibits a mosaic of archaic and more advanced traits. A few of these fossils have even been considered as belonging to *Homo erectus* or *Homo heidelbergensis*. Some of the morphological features of some specimens might reflect the transition between earlier populations (the paleospecies, *Homo erectus* and *Homo heidelbergensis*) and anatomically modern *Homo sapiens* or probably resulted from interbreeding between the paleospecies, *Homo erectus*, *Homo heidelbergensis*, *and Homo rhodesiensis*. Generally speaking, the lithics associated with archaic *Homo sapiens* of China are of Mode I technique, while the stone artifacts associated with the African archaic *Homo sapiens* are Acheulean, Levalloiso-Mousterian, or Middle Stone Age.

Architectural Sites: Monitoring

May Shaer
Amman, Jordan

Introduction

Monitoring is a crucial component of integrated site management planning, whereby, along with maintenance, it comprises one of the main policies that follow the stage of assessment and analysis of a site (Demas 2002: 45; Walton 2003: 6). The monitoring of architectural structures is not an end by itself, but is an important step in diagnosing the problems facing a structure, which would help in setting up appropriate interventions to remedy the situation. Hence, depending on the specificities of a site, the approach for monitoring its condition is established accordingly.

Definition

Architectural sites are those that comprise architectural elements or structures, which are typically referred to as archaeological sites and could date back to ancient times. Monitoring of these sites includes gathering data related to its condition over a period of time in order to understand the changes that occur on it as well as the factors that impact its condition. Issues related to the sites conservation, exposure, and visitor accessibility are factors that impact its long-term condition. Assessment of these issues helps to establish actions that are necessary for ensuring a site's conservation.

Key Issues/Current Debates/Future Directions/Examples

Monitoring is considered a significant step within a comprehensive process that aims at ensuring the sustainable conservation of a site. It follows assessing its existing physical condition and, often, should precede planning for designing and executing the appropriate interventions. Condition assessment is critical to establishing the baseline data that is necessary to monitor future changes to a site (Demas 2002: 39).

Monitoring programs can impact the way a site is managed. They help identify threats and risks at a particular site and hence provide the necessary criteria for designing priority actions in terms of mitigation and intervention measures. Additionally, such programs may potentially impact visitation at a site, in terms of numbers of visitors allowed at a certain hour, the paths that the visitors take, and, sometimes, even taking the decision to close off a site from visitation. Therefore, on the basis of a site's condition, the decision for the need and type of monitoring program would be considered and may precede any intervention measures. All of these factors should be considered when planning the management of a site, which also includes the tourism management aspect.

The Operational Guidelines for the Implementation of the World Heritage Convention (UNESCO World Heritage Center 2012) stresses the necessity of having a set of "key indicators" to be used in monitoring the state of conservation of properties. These indicators would be used to provide updated information on the condition of sites and are numerical when possible. The choice of indicators would depend on the nature of the site. Examples could be the percentage of buildings requiring urgent intervention, the degree of movement in a building, or the rate of increase or decrease of an encroachment at a particular site (UNESCO World Heritage Center 2012: 111). Moreover, the ICOMOS Charter on "Principles for the Analysis, Conservation and Structural Restoration of Architectural Heritage" (ICOMOS 2003) states that the quantitative approach to diagnosis is carried out on the basis of monitoring, in addition to testing and analysis. Hence, monitoring can be considered as being critical to ensuring appropriate site management planning.

Prior to initiating a site's monitoring activity, a specific methodology should be devised based on the specifics of the site and its condition status. Walton (2003: 9–16) mentions a number of

methods used for monitoring the condition of archaeological sites in New Zealand. These comprise a review of existing previous records that can be used to compare a site's previous situation with the current one; the preparation of forms that can be used as a checklist to assess the current condition and the causes of damages that occur; mapping, which is crucial to assess and monitor condition; and photographic recording.

Monitoring of architectural sites implies the monitoring of its built features, which can include its standing structure of walls and roofs, its foundations, and its finishing materials or decorative surfaces that it comprises. Finishing materials and decorative surfaces would include constituents such as tile cladding, stucco, and wall paintings.

The methodology for monitoring architectural sites may include visual inspection, survey and documentation, and the quantitative recording of specific data. However, prior to the collection of monitoring data, it would be pertinent to acquire the baseline information (Walton 2003: 8), upon which the future periodic monitoring would depend. The baseline data provides the necessary information on the existing condition of the structure and its features and helps to establish the main features to be monitored. It also establishes the criteria and methodology for monitoring. Sometimes, existing available records help to assess the state of conservation of structures by analyzing the rate of its deterioration, if any, and could lead to understanding the causes that might have led to that state. Accordingly, the methodology for monitoring can be devised, which would help in determining the future actions to be undertaken in order ensure its future conservation (Demas 2002: 39). However, in order to ensure a certain level of consistency in the collection of monitoring data, forms are often used, which include an outline structure for the registration of specific information.

The decision concerning what should be monitored depends on the condition assessment carried out and the causes of damages identified. For example, at the World Heritage Site of Petra, the impact of visitors was noted as one of the possible factors for the erosion of sandstone monuments. Hence, two areas in Petra were monitored over a period of 10 years by Tom Paradise, who found that a factor of erosion can be due to human contact (Responsible Tourism n.d.). Such assessments have now been developed by linking them within a geographic information system (GIS) that can be used as a monitoring tool, whereby information was obtained and mapped out with tourist numbers and movement at the site, in order to assess and understand their impact along the paths they took (Paradise 2012).

In fact, GIS systems are increasingly being used as a tool for the management of sites, including their monitoring. GIS applications allow the collection and referencing of information and ensure the regular monitoring of monuments (Tantillo 2007).

In recent years, a number of modern techniques have been developed to acquire quantitative data for accurately monitoring the changes occurring on the condition of architectural elements. For example, the monitoring of monuments and decorative surfaces through an active stereo vision system that provides the possibility for acquiring accurate chromatic measurement of 3-D surfaces of a feature has been developed (Grattoni et al. 2002: 383–90).

Particularly, with regard to architectural sites, cracks can be an important indicator of the condition of a structure, and hence the monitoring of crack movement would help in determining a building's stability. For monitoring the movement of cracks, telltales and sensors can be used, which are sometimes connected to automated data loggers. Based on the results acquired, the information is analyzed and diagnosis is thus carried out. This is a necessary step prior to designing any remedial interventions.

Other methodologies for the monitoring of decay on architectural surfaces may include regular sampling and testing, as, for example, in a procedure for measuring gypsum efflorescence on surfaces undergoing capillary rise to monitor decay resulting from salt crystallization on wall paintings (Zehnder 1996: 1669–78), which allows to determine the extent and rate of deterioration, and can define whether a decay activity had ceased following specific treatments and interventions.

Monitoring helps not only to detect the changes which occur on architectural features and buildings but also to identify the potential threats that could be of an intrinsic nature, that is, within the structure itself or those which are considered as external. All such information would help to establish a set of conservation interventions that would help in remedying the situation and arresting potential threats. Nevertheless, the process of monitoring does not end at that stage. Quite often, and while the execution of interventions is carried out, monitoring might be necessary, especially when interventions are related to structural issues. Also, following the execution of conservation work, the monitoring methodology should be revised on the basis of the changes that have occurred and the new condition status. Hence, monitoring should be perceived as an ongoing process that is carried out according to an established methodology and is continuously revised in accordance with a site's condition and current needs.

Architecture, Roman

Dirk Booms
Department of Greece and Rome, British Museum, London, UK

Introduction

One of the most tangible remains of the Roman Empire is its distinct architecture: with complete buildings still standing in every corner of the empire, the Romans have quite rightly received fame as master builders and engineers. They revolutionized the art of building through

experimentation and innovation, two talents Pliny the Elder already describes as innate to their culture (Pliny, *HN* 36.101; Boethius and Ward-Perkins 1970: 3). This entry will not focus on enumerating building types, which recently have been majestically treated by Pierre Gros (1996 and 2001), or building materials and construction techniques, of which the standard publication is still that of Jean-Pierre Adam (1984). Instead, it considers a handful of specific developments and processes that created the architectural style that we now interpret as properly Roman.

Definition

A subject as large as "Roman architecture" has had many interpretations in the past and can be difficult to define with precision. In the broadest terms, it could pertain to any structure that was built in the city of Rome or by the Romans, and in such a case the account would have to start in the tenth century BCE, when the first Iron Age huts appear on the Palatine Hill. Furthermore, the first monumental architecture in the city, in the sixth century BCE, is entirely Etruscan in style. It was, however, submitted to Greek and Hellenistic influences during the fourth and third centuries BCE and further innovation under Augustus to finally find its own unique form. The identification of "Roman architecture" adopted in this entry is that specific style that has its origins in and around Rome in the third century BCE, with roots in foreign architectural practices, but which through experimentation and innovation developed into a style that can be considered truly Roman.

Historical Background

The further Hellenization of the Etrusco-Italic architecture in central Italy during the second and first centuries BCE and its resulting hybrid styles were eventually known as "*consuetudo Italica*," a term used by Vitruvius (V.11.1), the most famous of Roman architects. It is in this architectural tradition that he composed his treatise *De Architectura Libri Decem* (Ten Books on Architecture), the only surviving architecture manual from antiquity and, as far as we know, the first to consider architecture in general. Previous works, only known through citations in his text, were all Greek and related only to specific orders or buildings. Vitruvius himself, on the other hand, wrote a wide-ranging architectural manual, which not only enumerates building types and rules of thumb for their construction but also provides information on the ideal education and talents of architects, their duties and responsibilities, and their social status. As such, his treatise can be seen as the first to provide a historical narrative regarding the art of architecture.

Writing during the reign of Augustus (27 BCE to CE 14), he dedicated his book in the later years of the first century BCE, when new forms of architecture started to take shape following the application of new building materials, the growing confidence in architectural know-how, and the development of a new ideology (see below). As said, his work displays a thorough knowledge of Greek building practices and a certain partiality to conservative Republican traditions: he frequently refers to the writings of Greek architects, and his chapter on temple design is almost entirely embedded in Greek tradition. He furthermore ignores marble as a building material or the use of the Corinthian order in its developed Augustan form, both of which novelties were becoming standard practices in Rome by the time of his writing. Elsewhere, however, he clearly distinguishes between Roman and Greek architectural forms, for example, for theaters and domestic architecture. Such seeming contradictions between his writing and contemporary practice have made some scholars question Vitruvius' applicability to the field of Roman architecture, but in other's eyes, this trait has made him all the more valuable, as his work perfectly describes the crossroads that architectural practice found itself in at the close of the first century BCE (Anderson 1997: 3–15, esp. 5; Rowland and Howe 1999: 8–18).

Key Issues

It would be quite impossible here to give a complete overview of what Roman architecture was and encompassed, and for a thorough overview, one should still consult the unsurpassed *Etruscan and Roman architecture* (Boethius and Ward-Perkins 1970). Rather, in this section, I will focus on the different mechanisms at play before and after Vitruvius, explaining why architecture developed as it did and why we still recognize buildings as "Roman" while they are thousands of miles apart:

(a) Experimentation and innovation: building materials and techniques
(b) Organization and specialization: the "mechanization" of the trade
(c) The Augustan Revolution
(d) Imitation and emulation: Roman architecture in the provinces

Experimentation and Innovation: Building Materials and Techniques

After the Punic wars in Italy, the moralist rejections of the Greek influence of the late third and second centuries BCE could not prevent the luxuries that Romans encountered in the Hellenistic kingdoms from permeating into every aspect of daily life. Rome embraced a significant influx of architects from the East – a move noticeable for centuries as many architects still had Greek names – but did not fail to produce skilled architects itself: in 174 BCE, the Seleucid king Antiochus IV commissioned Decimus Cossutius, an architect from Rome, to complete the long-unfinished Olympieion at Athens (Gros 1983: 434; Anderson 1997: 22). The Roman drive for innovation was immediately visible as Cossutius changed the temple's style from Doric to Corinthian and the building material from local limestone to Pentelic marble. As Cossutius came from an influential family of architects, it is not unthinkable that he and this project in turn influenced architecture at Rome itself: there, the very first marble Corinthian temple, the Temple of Jupiter Stator in the Circus Flaminius, known from literary sources, was built only shortly afterwards, in 146 BCE, by the Greek architect Hermodorus of Salamis for Caecilius Metellus Macedonicus. It was followed at the end of the century by the earliest surviving marble Corinthian temple in Rome, the round temple by the Tiber.

This constant exchange of people and ideas between the Greek and Roman spheres led to further experimentation with arch and vault, two concepts never fully explored by previous cultures. Sometime during the latter half of the second century BCE, a completely new type of arch was successfully built within the new city walls of Falerii Novi that would then be commonly used until the early Empire (Boethius and Ward-Perkins 1970: 101–2). It is but an example of this bold experimentation that caused the Romans to achieve supremacy in building. While they probably learned the arch from the Etruscans, its potential was only realized under Hellenistic influence, and the increasing pressure for new building types (most of which originate from or start being built in this period, such as theaters, basilicas, baths, and warehouses), as well as important innovations in the composition of mortar, made them eventual experts of vaulting techniques. Mortar was used for walls as early as the third century BCE, but the real innovation lay in the addition of a new type of volcanic sand, pozzolana – its name revealing its origins near Puteoli in the Bay of Naples – to create a type of concrete which was not only stronger than the previous mortar but also waterproof and could cure underwater (MacDonald 1965: 3–5).

As confidence in this new substance grew, the Romans started to use it for the natural expansion of the arch, the barrel vault, and subsequently many other types of vaulting. Early surviving examples of the new technique show its success (the second century BCE vaults of the Stabian Baths in Pompeii are a good example), but perhaps the most important step in the barrel vault's development occurred when the new techniques were used for the substructures and buttresses of a specific group of sanctuaries in Latium: the Sanctuary of Fortuna Primigenia at Palestrina (Fig. 1), of Hercules Victor at Tibur, of Juno at Gabii, of Jupiter Anxur at Terracina, and the Tabularium,

Architecture, Roman, Fig. 1 The Sanctuary of Fortuna Primigenia at Palestrina. (Boethius and Ward-Perkins 1970: 142, Fig. 78)

recently identified as the terrace for such a sanctuary in Rome. All date from the late second century BCE to the early first century BCE (Coarelli 1987, 2010: 129; Lancaster 2005: 5). Unmistakably based on the Hellenistic sanctuaries in the East, for instance those of Asklepios at Kos or of Athena at Lindos (Rhodes), they are very distinctly Roman in character, not only through this novel use of materials and vaulting techniques but also by the way in which they altered the landscape.

While their Greek precedents were built on terraces on natural substructures in dugout hillsides, using the curves of that landscape, as at Kos and Lindos, Romans used concrete, arches, and vaults to artificially alter – and ultimately, in their eyes, enhance – the landscape, implementing strict axes and symmetries and building upwards (Boethius and Ward-Perkins 1970: 122). The technological possibilities that architects acquired from these Latial sanctuaries made it possible for the Romans to build, in 55 BCE, the Theater of Pompey, the first completely freestanding stone theater in Rome, which used the same arching and vaulting techniques, though with updated materials. Further studies lent a profound understanding of building materials and paved the way for bold projects like the Domus Aurea, the Markets of Trajan, and the sophisticated design of the dome of the Pantheon. The deliberate choice to use different types of aggregate in the concrete of the building and dome, so the weight decreases as

Architecture, Roman, Fig. 2 A section of the Pantheon. (Lancaster 2005: 62, Fig. 46)

the height increases, was experimented on in the earlier Baths of Trajan, but perfected in the Pantheon (Fig. 2), ultimately contributing to the fact that the building is still standing today. It was subsequently used for the largest vaults and domes, as at the Baths of Caracalla, the Baths of Diocletian, and the Temple of Minerva Medica (Lancaster 2005: 158–61).

Organization and Specialization: The "Mechanization" of the Trade

Key to the development of new techniques and building types is not only the drive for experimentation and a thorough understanding of the capacities of one's building materials but also the availability of resources, their potential for easy handling on-site, and most of all, an established and well-organized framework in which to operate. Unfortunately, there is a distinct lack of ancient sources on the actual on-site duties of the architect, contractor, or other master builder in the Roman period, even with the survival of Vitruvius' handbook. We are better informed about the Greek Classical Period, when architects were mentioned in the publicly displayed building contracts for major temples. For a long time, the *architekton* was an occasional occupation, only required for large projects such as temples and stoas, which were only commissioned once every generation (Coulton 1995: 27–9). In the Hellenistic Period, the emergence of the new monumental building types and the wealth of individual patrons and new kingdoms, rather than the *polis* as commissioner, gave rise to architect becoming a proper full-time profession, sometimes under permanent patronage. Ironically, such craft specialization also brought with it the anonymity of the architect (but not yet a loss of prestige), as from then on and continuing into the Roman period, the most important name to remain attached to a building was that of the patron. Good examples are the Attalid kings at Pergamon, Pompey and his Theater, Agrippa and his Pantheon, or Maxentius and his basilica. And thus, to identify Roman architects of the late Republic, we depend mainly on evidence from tombstones and other inscriptions or passing references in Cicero, Vitruvius, and other contemporary writers. Generally, it appears that, especially but not exclusively for small construction projects, architects were at the same time designer, master builder, contractor, and on-site supervisor site (Gros 1983: 431, 452).

With the specialization of the job also came a specialization of the trade. Construction sites became much better organized, with both unskilled labor and highly skilled workmen (*fabri*) contracted for specific tasks. Among these, one would find the *mensores* or surveyors to set out the site, *fabritignuarii* to build the walls, the *tectores* as plasterers, and the *redemptor* – the contractor – to supervise. The Roman building trade was organized with military precision: the guild of builders (the *collegium* of the *fabritignuarii*) at Ostia had reached 350 members by the end of the second century CE; in Rome it had around 1350 members at the same time. Ordinary members were called the "body of booted soldiers" and were divided into 16 cohorts in Ostia, 60 in Rome, each headed by a *decurio*,

while the patron of the *collegium* was a *praefectus*. What is most surprising, however, is that the 350 members of the guild in CE 198 were men of high status: patrons themselves or at least contractors, architects, and heads of "firms" who could afford to pay the entrance fee. This shows that the entire body of builders must have been significantly larger, even at a relatively small town like Ostia. There can be no doubt that by the end of the second century CE, building must have been a very lucrative business with a possible 20,000 people active at any one time in Rome alone (DeLaine 1997: 197–201, 2000: 121, 132), which must have been a continuous building site for the majority of two centuries.

Advantages of such a military organization are obvious: ultimately, it would lead to more uniform construction techniques as well as a quick output rate. Another important change that led to these developments took place with the invention of Roman concrete, as set out above: concrete walls needed an outer facing, and a standardization of the process would mean faster and stronger building. Vitruvius (II.8.1–4) tells us about two facing techniques of his time: the old-fashioned *opus incertum*, in which tufa blocks of irregular size were fitted into an irregular pattern, and the then new *opus reticulatum*, where square-faced tufa blocks were placed in diagonal lines (Fig. 3). The Latial sanctuaries still show *opus incertum* in their walls, but reticulate took over soon afterwards and it is fair to say that it created a shift in Roman building practice: for the first time in the building trade, it is possible to speak of mass production. Since all reticulate blocks were the same shape and size, they could be mass-produced by organized teams of stone cutters, possibly even slaves. This had several consequences: specific skill was needed at the quarry to cut the reticulate blocks, as opposed to the irregular-sized *incertum* blocks, and the mason's time to place the blocks while building walls was reduced significantly. This complete mechanization of the construction site led to the decline in the little prestige that the *architectus* had enjoyed during the late Republic, and in the early Empire his job was basically reduced to that of the *redemptor* or contractor (Torelli 1995: 227–230). The only exceptions are, unsurprisingly perhaps, architects that can be linked to specific emperors and designing, rather than executing, grand imperial projects in the first two centuries CE: Celer and Severus for Nero, Rabirius for Domitian, Apollodorus of Damascus for Trajan, and Hadrian himself (for their careers, see Anderson 1997: 52–67).

As the standardization and mechanization continued, we notice the appearance of specialized "ateliers," where building materials could be ordered and bought prefabricated, as opposed to custom commissioned per new project. Nowhere is this more visible than in the use of fired brick and marble. Fired bricks were first used in the early first century BCE and retained the standard

Architecture, Roman, Fig. 3 Examples of *opus incertum* in the Sanctuary of Jupiter Anxur in Terracina, of early *opus reticulatum* in the Theater of Pompey in Rome, and of developed *opus reticulatum* in the Baths of the Trinacria in Ostia, Italy. (Photos by author)

Architecture, Roman, Fig. 4 Map of the main marble quarries in the Roman Empire. (DeLaine 1997: 95, Fig. 54): *1*. Luna, *2*. Pentelic, *3*. Proconnesian, *4*. red porphyry, *5*. Mons Claudianus granite, *6*. Aswan granite, *7*. Troad granite, *8*. green porphyry (*serpentino*), *9*. Numidian (*giallo antico*), *10*. Thessalian (*verde antico*), *11*. sizes given to them then, hence the uniformity one can detect in Roman brick buildings that are still standing. But not only were their size and triangular shape standardized; occasionally also signs of a mechanized production process are visible from stamps that carry the name of either the owner (of the brickyards or *figlinae*) or the maker. In the late first century CE and firmly from CE110 onwards, bricks were more regularly stamped with date and names of the owner, of the brickyard, and sometimes even of the slave that made them. These owners were part of the elite, but over time (and definitely by the beginning of the second century CE), most brickyards became the property of the imperial family, causing further uniformity in production and acquisition processes (DeLaine 2000: 134).

Around this time, the same thing happened to the marble trade. The Romans' first acquaintance with the stone occurred via the marble statues and architectural elements that were looted as war booty from Greece and the East in the second century BCE. Its popularity grew quickly, and already Caesar, under whom the quarries for white Carrara marble were opened up, started taxing marble as a luxury good. Unlike the Greeks, however, Romans especially favored colored marbles for decorative purposes, almost all of which were quarried outside of Italy (Fig. 4). Triggered by the annexation of Egypt as Augustus' personal property, including its quarries of red porphyry and gray and pink granite, the potential economic benefits were soon realized and by the middle of the second century, almost all the major quarries in the provinces entered the hands of the imperial family. With this monopoly came a first significant reorganization of the marble trade, now overseen by imperial officials, and the processes of extraction, transportation, and sale were rigorously controlled and inspected. At a later stage, production (and accompanying revenue) was even further increased by the focus on mass production of half-finished products (e.g., sarcophagi) and on the creation of stocks, rather than on individual orders and individual building projects. Exploitation of the quarries reached new heights because of these changes: it is estimated that between 100 and 160 CE, the quarries at Dokimeion, Turkey, produced over 500,000 m^3 of marble (Waelkens 1990: 61–72). Long-distance trade in decorative stones on this scale remained unique prior to the modern period.

The Augustan Revolution

After two centuries of building in the newly created Hellenistic-Italic way, the reign of Augustus gave rise to the development of a new decorative program in Rome, which from there spread throughout the Roman world and ultimately defined what we still recognize today as "Roman." This was not a total break with what went on before: the same building types continued to be built, while building techniques continued to develop along the lines explored above. But it is obvious from Augustus' testament, the *Res Gestae Divi Augusti*, that he invested heavily in architecture, cleverly using it as another – successful – propagandistic tool and part of the implementation of an official visual language in his reorganization of Roman society, which he applied to every aspect of daily life, from coins to wall paintings to silver drinking cups (Zanker 1987). In order to legitimize his rule, Augustus needed to exhibit certain continuity between the old Republic and the new order and particularly achieved this through architecture: by evoking a partly Greek classical past in a new jacket, Augustus confirmed that Rome culturally equaled, if not surpassed, Greece.

This architectural innovation deliberately focused on specific building types, most notably temples and theaters. Early instances of the new style can be found at the Temple of Apollo Palatinus (36–28 BCE) and the Temple of Apollo Sosianus (almost contemporary and identical in execution), but already immediately after, it found its characteristic incarnation in the Temple of Mars Ultor (started in the 30s BCE) in the Forum of Augustus, dedicated in 2 BCE (Fig. 5). Many characteristics of its design and decoration became the norm and embodiment of the new Augustan architecture: it was completely built from Carrara marble (not just marble-clad); it incorporated the Romans' predilection for frontal views (as opposed to the Greek viewability from all sides), in this case by a *peripteros sine postico* plan (i.e., with columns only on three sides); it rose on a high podium (an incorporated Italic custom); and above all, its Corinthian order had been transformed into the developed Roman Corinthian, which among other minutiae included a heavy focus on acanthus leaves (which became

Architecture, Roman, Fig. 5 (**a**) Comparative plans of the Temple of Apollo Sosianus, Temple of Mars Ultor, and the Maison Carrée. (Stamper 2005: 120, Figs. 89, and 133, Fig. 97); (**b**) reconstruction of the Temple of Mars Ultor. (Boethius and Ward-Perkins 1970: 190, Fig. 85) and a photo of the Maison Carrée. (Zanker 1987: 256, Fig. 201)

omnipresent in Augustan art) and a new type of cornice enriched with modillions and coffering, finally giving the Corinthian order its own cornice, which it never had in Greece (Gros 1996: 145–47; Wilson Jones 2000: 139–42). Furthermore, whereas before the outside appearance of a temple needed visually to be the most impressive (following Greek and Hellenistic customs, as one still sees at the sanctuary of Fortuna at Palestrina), now the interior grew in importance and was decorated accordingly, with different types of lavish colored marbles for both flooring and the multistoried columnar displays along the walls. It is likely that in the new visual imagery, the different marble types were representations of the different geographical regions they came from, by then all Roman provinces. In short, the use of multicolored marbles stood symbol for the wealth, breadth, and power of the Roman Empire under Augustus or, even, the *Pax Augusta*.

Apart from temples, theaters also became the carriers of the new Augustan ideology. The Senate had only recently allowed the construction of permanent theaters in Rome, and thus they had a lot of potential to allow for innovation and manipulation. In the Campus Martius, Augustus constructed no less than three theaters (of Marcellus, of Balbus, and a thorough restoration of that of Pompey), together with other places for entertainment, the Saepta Julia and the amphitheater of Marcus Scaurus, in all of which he frequently mixed with the people (Zanker 1987: 151–57). Although this was a less subtle display of propaganda, it obviously pleased the people and the success of the theater was exported to every outpost of the empire; together with temples, they proved to be perfect vehicles for the dissemination of the Augustan ideology, and in one of those instances where Vitruvius (V, 3–9) seems to have been favorable of contemporary developments in architecture, he devotes a disproportionate amount of text on the Roman theater.

Imitation and Emulation: Roman Architecture in the Provinces

It is therefore not surprising to see the same architectural developments arise outside of Italy during the principate of Augustus. Before this time, Rome had only marginally, if at all, been involved in the architecture of the provinces. In the East (Greece, Asia Minor, the eastern Balkans, and Cyrenaica), a sophisticated, Hellenistic architectural tradition had existed for centuries, while in the West (Spain, Gaul, western Germany, Britain, and western North Africa), architectural traditions were poor and one could argue that any sign of monumentality was lacking. It is only to be expected that local influences and traditions continued to reverberate through the Roman occupation, but it is quite an achievement that today, we would instantly recognize cities or buildings as Roman from their architectural remains, even if they were located thousands of miles apart and had significantly different cultural backgrounds.

Both Spain and the south of France (*Gallia Narbonensis*), although part of the Roman Empire since 206 and 121 BCE, respectively, only received a distinctive monumentalization in their architecture from Augustus onwards, and it is noteworthy that the early examples seem to have been directly inspired by what went on in Rome: the Maison Carrée at Nîmes (Fig. 5), the temple to Augustus and Livia at Vienne, and the temple to Rome and Augustus at Barcelona were all based directly on the Temple of Mars Ultor. At Nîmes, the decoration is even so similar to that of the Ara Pacis, the other Augustan propaganda monument in the Campus Martius in Rome, that the same architect and/or workmen are believed to have worked on it. This influence from Rome continued: in Italica (Spain), birthplace of Trajan and Hadrian, Hadrian built the Traianeum, modeled on the same temple, while at Avenches (Switzerland), an almost exact copy to the Forum of Peace of Vespasian was built in Flavian times (Gros 1996: 151–59, 170, 184).

That there was much room for regional experimentation and other cultural influences, however, is clear from case studies on the so-called forum-basilica complex. This building type, in which the forum was lined with a basilica on one side and the main temple axially laid out lengthwise, could first be found at Silchester (United Kingdom), Lugdunum Convenarum (Saint-Bertrand-de-Comminges, France), and Baelo Claudia (Spain) in the first century CE, not just imitating but also

Architecture, Roman, Fig. 6 Plans of the forum-basilica complex at Lugdunum Convenarum. (Bedon et al. 1988: 218) and of Trajan's Forum in Rome according to R. Meneghini. (after Stamper 2005: 177, Fig. 133) and reconstruction of the complex at Augusta Raurica. (Boethius and Ward-Perkins 1970: 343, Fig. 131)

improving and standardizing the model of the Italian forum. After the transformation, it was exported back into Rome to find its ultimate translation into the Forum of Trajan, only to be copied again in the provinces, as at Augusta Raurica (Augst, Switzerland) (Gros 1996: 220–3; Fig. 6).

In North Africa, where a limited monumental architectural tradition had existed before, a much more hybrid style emerged, as not two but three cultural spheres came together: Roman, Berber, and Punic. Here, Roman-style temples could be dedicated to indigenous deities and vice versa, but decorative details often remained Punic in style. A representative example can be found at Lepcis Magna, when between CE14 and 19, a temple to Rome and Augustus was built. Its Ionic order, heart-shaped angle piers, and wooden architraves were all remnants of an indigenous Punic tradition, but at the same time, the temple was peripteral *sine postico*, approachable from the front only, and rested on a tall, vaulted podium with flanking stairs (Boethius and Ward-Perkins 1970: 466–67).

Asia Minor, the wealthiest of the Eastern provinces, tells a different picture altogether. The province of Asia, though already an early "conquest" (it was given to Rome by the last king of Pergamon in 133 BCE), kept its architecture quite comfortably rooted in the Hellenistic tradition for more than another 200 years. Roman

Architecture, Roman, Fig. 7 Plan of the Temple of Augustus and Rome at Ankara. (Akurgal 1973: 285, Fig. 118)

influences only started to trickle down slowly and in a piecemeal manner in the Augustan era. The Temple of Augustus and Rome at Ancyra was so rooted in Hellenistic fashion that it was once considered to have been built in the second century BCE (Fig. 7), while the contemporary Temple of Augustus and Men at Pisidian Antioch (but not the surrounding portico) followed the styles laid out at Rome, down to the details of the acanthus leaves. From Flavian times onwards, more hybrid structures with heavy influences from both backgrounds emerged. The Temple of Domitian at Ephesus and the Antonine Sanctuary of Zeus at Aizanoi are Ionic pseudodipteral temples (which pretend to have two rows of surrounding columns, but only have one), similar in style to the temple at Ancyra, but both were raised on a high podium (Boethius and Ward-Perkins 1970: 389–92; Lyttelton 1987). When pure Roman buildings arose, they are often directly linked to imperial involvement: an example is the Sanctuary of Asklepios Soter in Pergamon, the patron of which, Lucius Cuspius Pactumeius Rufinus, Hadrian met and befriended on his first visit to the city in CE124. It is likely that the sanctuary was dedicated in CE 129, on Hadrian's second visit, by which time it also included an exact half-scale copy of the Pantheon in Rome (Gros 1996: 182–183). By CE 142, Rufinus had achieved his goal of becoming consul in Rome.

This reluctance to take over Roman architecture wholesale probably lay at the base of the emergence of a specific type of architecture now commonly referred to as "marble style." The abundant availability of marble in the provinces of Greece, Asia Minor, and North Africa; the emergence of a rich elite in late Flavian and early Trajanic times; and the desire to compete not only between cities but also for political positions in Rome gave rise to a construction frenzy of monumental buildings for public use. While Rome was still turned to for inspiration, the style is very much a provincial emulation of what was contemporary custom in Italy. Based on the stage buildings of theaters in Rome (especially those of Scaurus [Pliny *HN* 34.36] and of Pompey), spectacular columnar facades of multiple orders and multiple marble types now started to appear in other buildings: monumental fountains or *nymphaea* (e.g., Olympia, Miletus [Fig. 8], Ephesus, Perge, Lepcis Magna), honorific arches (e.g., Lepcis Magna, Perge, the Arch of Hadrian at Athens), bath buildings (where a central room with this feature is now often called "Marmorsaal," e.g., Sardis and the Harbour Baths at Ephesus), and other public buildings (e.g., the Library of Celsus at Ephesus). It was only exported into Rome at a later stage, perhaps not coincidentally when under Septimius Severus (CE 193–211), the emperor from Lepcis Magna, a monumental fountain at the foot of the Palatine, called the Septizonium, was

Architecture, Roman, Fig. 8 Reconstruction drawing of the *nymphaeum* at Miletus. (Boethius andWard-Perkins 1970: 404, Fig. 153)

constructed in this style (Boethius and Ward-Perkins 1970: 403–6).

Conclusion

It is clear that these four "drivers" can explain most of the development in the architecture in the Roman Empire. While stronger local influences survived in some places and unique variations exist everywhere, overall this consistent style of forms was established which today allows us to recognize structures all over Europe, North Africa, and the Middle East as part of the same architectural tradition.

Future Directions

Still acutely lacking in architectural studies is a thorough examination of the non-Etruscan, local Italic traditions in Italy at the advent of and during the Hellenization of the architecture. This transition has never been fully documented and the standard work on Hellenistic buildings of Italy is now over a century old (Delbruck 1907). More positively, recent decades (1990s and 2000s) have seen a still continuing shift of focus from the 1960s and 1970s increase in books on urbanism and building types to the neglected field of the constructional aspects of Roman architecture, including detailed studies on the way building sites were organized and on identifying individual groups of builders in the same building or town (e.g., DeLaine 1997; Lancaster 2005). New excavations, as well as never-executed detailed studies of even the most famous monuments, will contribute heavily to this research in the coming years.

Archival Research and Historical Archaeology

Russell K. Skowronek
University of Texas-Pan American, Edinburg, TX, USA

Introduction

> Historical archaeology is a multi-disciplinary field that shares a special relationship with the formal disciplines of anthropology and history, focuses its attention on the post-prehistoric past, and seeks to understand the global nature of modern life (Orser 2004: 19).

Few archaeologists would have self-identified as a "historical archaeologist" before 1960 (Harrington 1952, 1955). In that year Stanley South started the Conference on Historic Sites Archaeology in conjunction with the Southeast Archaeological Conference. Later, in 1967, the Society for Historical Archaeology was founded. Yet, by that date, there had already been more than a century of what has been termed "text-aided archaeology" (Little 1992) in the Old World on Biblical, Chinese, Egyptian, Greek, Roman, and more recent medieval and post-medieval sites, and in the New World on ancient Mayan and early modern colonial sites in both terrestrial and underwater contexts. Most of these early endeavors were conducted with an eye toward sites associated with elites and were focused on historic preservation and site interpretation, that is,

to provide artifacts for display and evidence for reconstruction. Over time these evolved into numerous subfields (e.g., classical, medieval, maritime) while retaining their focus was on the post-prehistoric or historic, literate societies (Fontana 1965; Schuyler 1970). In the United States the historic preservation movement created an interest in sites of the historic period starting at such renowned sites as Williamsburg and Jamestown in Virginia and Fort Necessity in Pennsylvania.

In English-speaking North America the focus on the birth of the early modern global economy steadily began. Methodologically, "historical" archaeologists draw equally on both archaeological and documentary records to consider the processes associated with cultural continuity and change in the face of modernization and in giving a voice to those who were largely mute in the documentary record – women, people of color, children, and the poor. In 1977, the publication of South's method and theory book brought historical archaeology into a reliance on empirical patterns and systematic analysis of archaeological materials. Today historical archaeologists use the methods of history, anthropology, and archaeology to study the past. That is, to paraphrase Schuyler (1977), they use the written word, spoken word, observed behavior, and preserved behavior in their research.

Definition

Archives, simply put, are repositories in which public records or other primary historical records are stored. This may range from the great national archives such as the National Archives in the UK (http://www.nationalarchives.gov.uk/), formerly known as the Public Records Office located in Kew outside of London; the US National Archives and Records Administration (http://www.archives.gov/) located adjacent to the Capitol building in Washington, DC; the French Archives nationales, especially the overseas territories division (*Archives nationales d'outre mer*) (http://www.archivesnationales.culture.gouv.fr/); or the Archivo General de Indias in Seville (http://www.mcu.es/archivos/MC/AGI/index.html) where documents pertaining to four centuries of Spanish exploration and colonial administration are housed. Smaller repositories may focus on businesses (e.g., Hudson Bay Company Archives in Winnipeg), labor (e.g., George Meany Memorial Archives in Silver Spring, Maryland), the lives of specific individuals (e.g., Ludwig Beethoven at the Ira F. Brilliant Center for Beethoven Studies at San Jose State University in California), or places (e.g., the Louisbourg Institute of Cape Breton University; Santa Barbara Mission Archive-Library). In several European countries, there can be regionally run archives – in the England, for instance, each county has its own records office which holds archives especially pertaining to county matters, although not exclusively so. Regional and even local libraries may also have archival holdings. Sometimes primary documents are published such as those relating to French seventeenth-century trade items in the Illinois country (Pease and Werner 1934) or invoices for the Presidio of Santa Barbara (Perissinotto 1998). These provide researchers and students with real-world "touchstones" for the material culture of the fur trade or the Spanish colonial frontier, respectively.

The "written word" can include contemporary plans and insurance maps; newspapers; vital records concerning such matters as deaths, burials, marriages, and baptisms; deeds; probate inventories; census data; ethnohistorical and geographical accounts; and quantifiable documentary evidence including those relating to the value of exports, port activity, custom's duties, and expenditures for defense. All are especially useful for situating people and their associated settlements within the larger culture and world economy. For example, invoices, ledger books, reports, and eyewitness accounts have been used to identify artifacts and features found at Spanish California mission and presidio sites (Skowronek and Thompson 2006) and have been used to create ethnohistories of Native Peoples in the region (e.g., Hoover 1977).

Other forms of useful documentary evidence include contemporary letters and bureaucratic reports. From piracy and related economic concerns to diet and disease, documents have enormous descriptive value for the picture they paint of a community and the concerns of portions of

the populace. Additionally, these reports and letters may contain information on the construction and condition of buildings and vessels. This information might be used to chronicle building phases of a structure or to identify a shipwreck on the basis of the presence or absence of certain aspects of material culture. HMS *Fowey*, lost off the Cape of Florida in 1748, was identified using a combination of court martial proceedings and other primary documents using this technique (Skowronek and Fischer 2009). While documentary evidence can provide a revealing look at the options and choices available to past peoples, they do have limitations which often can be addressed by an analysis of the presence or absence of material evidence. For example, in the sixteenth-century letters from Santa Elena and St. Augustine in the Florida colony, there were complaints that when it came to diet only "vermin and scum" were available to sustain the communities. In fact, study of faunal and floral evidence demonstrates that a wide variety of both domesticated and wild comestibles were available to the settlers (Reitz and Scarry 1985). Other sixteenth-century Spanish communities vociferously complained of seemingly endless attacks by pirates or a continuing problem of smuggling. Study of the material culture from these sites demonstrates that role of piracy and smuggling was overblown in these documents and by subsequent researchers. In fact, the presumed contraband formed a rather insignificant part of the material record, and the vast majority of what was found may well have arrived through fully legal avenues of trade (Skowronek 1992).

Oral history, once a mainstay of history, fell out of favor at the end of the nineteenth century among those studying the West and its colonies. By that time the written word was considered to be the absolute and definitive primary source of information on the past. With a growing number of archives and publishing outlets, historians and political leaders of the era saw any form of non-written material as a lesser and weaker form of evidence associated with preliterate societies and illiterate peoples. As a result oral history passed into the realm of anthropologists and folklorists. By the last third of the twentieth century, social historians began to turn back to oral histories and the evidence provided by other social scientists to study the past. Oral history can fill in the gaps on particular subjects about which there is little or no information. Oral history can complement both the documentary and archaeological records with human experience and perception (Newland 1997). One of the early landmark projects in the USA which demonstrated the strength of the various avenues of inquiry was conducted at the Mott Farm in Rhode Island (Brown 1978). This study combined documentary history, oral history, and archaeology to more clearly illuminate a 300-year-long picture of human-land interactions. The farm, dating from the seventeenth century, was owned by the Mott family to just before the turn of the twentieth century. For the next century, another family lived on the property renting a portion of the home to a series of families. Brown's study included the traditional study of primary documents associated with the Mott family which provided information on how that family economically fared in their 200 years on the property. This included study of tax records, probates, and personal records. While similar documents were available for the twentieth-century occupants, these were supplemented with oral histories conducted with surviving members of those families. From these, information on trash disposal, outhouse location, and other usually forgotten aspects of life were recorded and later confirmed in the archaeological record.

Key Issues

Scholars continue to struggle over the primacy of the material, written, and spoken records. Documents may be overvalued in the face of contradictory material evidence. Documents may be unsystematically and uncritically used. Oral histories and ethnographic and ethnohistorical accounts associated with the direct historic approach to studying the past may be taken as unchanging traditions. Finally, there are continuing misperceptions regarding the nature of "science" and "history" as being separate and not comparable (Feinman 1997). What this means in the study of the past is that documents should neither be used uncritically nor

given precedence over material culture. Rather, historical analysis should be conducted in a systematic and scientific manner which contextualizes the documentary and material records against both the regional and larger global communities in which they were created. Both are likely to have what Michel-Rolph Trouillot (1995) has termed "mentions" and "silences," and what is left out of a written or material record is often as informative as what has been included.

Some 50 years have passed since the use of documentary evidence in archaeology was formalized under the umbrella of historical archaeology. The founders of the field were trained as prehistorians in anthropology programs. Their first forays, and those of many of their students, into this endeavor were poorly received by their colleagues and historians as being neither history nor science. Now, a new generation of historical archaeologists has taken to the field versed in the social sciences and humanities and questioning the ideas promoted in the culture history, processual, and post-processual approaches. Today the archaeological, ethnographic, documentary, and spoken records are powerful methodologies for the examination of history through the lens of historical archaeology (Little 2007). By using these complementary and nonexclusive data sets a more accurate and unbiased view of past peoples, and their associated cultures may be discerned by those willing to undertake an interdisciplinary open-minded approach to understanding the past.

Physical Geography, Oceanography, and Climate

The Arctic Ocean is a unique place, with no analogue elsewhere on the planet. The world's largest confined ocean, its permanent sea-ice cover, creates a hostile and difficult environment for human research and occupation but is a crucial component of global climate and the ecology of the world ocean. The region's oceanographic characteristics, climate regime, and human adaptations are not matched by any other, and these factors have been emphasized in recent years as indicators of global warming bring dramatic changes to the Arctic.

Oceanographers consider the Arctic Ocean and its bordering seas to be the body of water surrounding the North Pole and bordered by Europe, Siberia, Alaska, Canada, and Greenland, occupying an area of approximately 14 million km^2 (Fig. 1). Major island groups are found off the European and Siberian coasts (Svalbard, Franz Josef Land, Novaya Zemlya, Severnaya Zemlya, and the New Siberian Islands) and throughout Canada's Arctic Archipelago. Bordering seas are the Barents, Kara, Laptev, East Siberian, Chukchi, Beaufort, Greenland, and Norwegian Seas. Broad and shallow continental shelves extend from the European and Siberian coasts and beneath the Chukchi Sea but are much narrower and deeper off Greenland and North America (approximately 30% of the surface area of the Arctic Ocean is underlain by continental shelves). Maximum depths are attained in the two main sub-basins of the Arctic Basin (the Eurasian and Canadian, with depths of c. 4200 and 3800 m, respectively). The Arctic Ocean is connected to the North Atlantic Ocean through Baffin Bay, and the Greenland and Norwegian Seas, and to the Bering Sea and North Pacific Ocean through Bering Strait. The largest rivers flowing into the Arctic Ocean are the Ob, Yenisei, and Lena (Siberia), and the Mackenzie (Canada).

The Bering Sea is bounded by Siberia on the west, Alaska to the east, and the Aleutian Islands chain to the south. The Bering Sea has its own special oceanographic characteristics, being neither Arctic nor temperate, with a fairly free exchange of water through the Aleutian arc with the North Pacific, and a quite restricted exchange with the Arctic Ocean through the narrow and shallow Bering Strait (c. 85 km wide and 45 m deep). In a typical winter, sea ice extends south to the Pribilof Islands but retreats north past Bering

Topographic map of the Arctic
(Source: CAFFs Arctic Biodiversity Trends 2010)

Arctic Ocean and Bering Sea: Maritime Archaeology, Fig. 1 Map of the Arctic Ocean and Bering Sea

Strait during the summer. The Bering Sea is one of the most productive marine ecosystems on earth, especially along its extensive continental shelves.

The Arctic climate zone can be defined in a number of different ways. Two of the most prevalent are by latitude (above 66.56° N, the "Arctic Circle") and by temperature (the region bounded by the 10 ° C summer isotherm) (both shown in Fig. 1). The climate of the Arctic is characterized by strong seasonality: long, cold, and dark winters and short summers with long daylight hours (Nuttall and Callaghan 2000). The climate of the ocean itself is shaped by the year-round presence of the Arctic pack ice and by the physical processes of freezing and thawing of river, lake, and sea ice. The presence of ice cover has major influences on physical and biological processes within the ocean and atmosphere, as well as implications for human use and occupation. The Arctic Ocean is almost entirely ice-covered during the winter, while minimum ice extent is attained in late summer. However, Arctic sea-ice cover has undergone significant changes in the past two decades, with record lows for both summer minimum and winter

maximum ice extent. The lowest seasonal minimum extent was recorded in September 2012 and the second lowest in 2016. The overall trend is toward shorter ice-cover seasons and thinner ice cover in general. These data have raised speculation that the Arctic Ocean may see entirely ice-free summers as soon as 2030 (Stroeve et al. 2012). The rapidly changing conditions in the Arctic have important ramifications for global climate, human presence and research, as well as the archaeological record of the region.

Historical Background

Exploration and settlement of the Arctic is a very recent endeavor in terms of overall human history, coming essentially at the tail-end of over a million years of human dispersal from Africa. In the later Pleistocene, between approximately 45,000 and 25,000 years ago, modern humans expanded north and east across Eurasia into new regions. These previously unexplored habitats included Siberia up to approximately 60° N (and potentially further on a seasonal basis). These areas were, however, largely abandoned during the peak of the Last Glacial Maximum (LGM, c. 20,000–18,000 years ago) (Hoffecker 2005). In Western Europe, the Fenno-Scandinavian glaciers began to retreat around 12,000 BCE, and the earliest occupations of Northern Norway are dated to c. 10,000 BP. Many of the regional cultures arising in Scandinavia during the Mesolithic show a clear orientation toward maritime subsistence. The vast expanse of Northern Eurasia was also reoccupied during the climatic amelioration following LGM, with a variety of Late Pleistocene and Early Holocene cultures arising across most of Siberia.

The growth of polar ice caps and continental glaciations during the Pleistocene resulted in sea levels lowered as much as 120 m below those of the modern era. During much of the Middle and Late Pleistocene, the shallow continental shelf between Siberia and Alaska was thus exposed as dry land. The exposed land connection is often referred to as the "Bering Land Bridge," and the region from eastern Siberia to the Yukon Territory, encompassing the now-submerged Bering Land Bridge, is called "Beringia" (Hadleigh West 1996).

The existence of a land bridge between Asia and North America (and adjacent areas of exposed continental shelf) is of paramount importance for understanding theories of human colonization of the Americas. Although the possibility of maritime migration has been proposed (Dixon 1999), prevailing theories favor an overland route for the first humans in North America. The oldest archaeological sites in Alaska date to c. 15,000 BP, and by c. 4500 BP Paleo-Eskimo peoples had settled in northern Greenland.

Successful settlement of the Arctic was dependent on a number of specialized technologies and adaptations, especially those designed and used for maritime subsistence (such as skin boats and toggling harpoons). Tools such as the needle (for use in tailored clothing and sewing skin boat covers) were prerequisites for survival in the Arctic. Equally important was deep and intense knowledge of the Arctic marine environment, especially sea ice. A succession of cultures can be seen across the North American Arctic, from Paleo-Eskimo to Dorset and finally Thule peoples. The Thule migration from Alaska across the Canadian Arctic to Greenland around 1300 CE is remarkable for its speed and distance – nearly 4000 km from Bering Strait to Greenland, occurring over a single generation and possibly over just a few seasons! One possible impetus for this "dash across the top of the world" may have been trade in metals and other goods with Norse inhabitants of Greenland. Archaeological investigations of sites in Canada and Greenland show undoubted contact between Norse and indigenous inhabitants of the Arctic. The cultural affiliation of the people who encountered the Norse in Newfoundland and Labrador is not certain, but in the northern areas, they were met by Thule Eskimos – the ancestors of modern Inuit peoples. The nature of these interactions is a fascinating topic, explored by archaeologists in Canada and Greenland (see Fitzhugh and Ward 2000; Maschner et al. 2009).

The oldest maritime sites in the Arctic are camps and settlements of prehistoric maritime

cultures. The faunal remains discovered in these sites suggest use of a wide variety of maritime resources: from intertidal mollusks and fish to seals, walrus, and whales. Construction of reliable watercraft was both a necessity and a challenge in the treeless circumpolar environment. Most indigenous peoples in the coastal Arctic used skin boats: open (umiaks) and decked (kayaks). The frames of both umiaks and kayaks were constructed of driftwood and covered, as a rule, with marine mammal skins. Ivory, bone, or antler frame members were also occasionally used, and in some cultures the cover was made of caribou and even polar bear skins. The frames were lashed with baleen and sinew.

The overall chronology of skin boat development in circumpolar regions remains uncertain. As a key element of subsistence, skin boat technology has arguably been used since the very beginning of human population in the region. Recent maritime migration theories suggest that skin boats might have been a vehicle of human expansion across Beringia c. 20,000–10,000 BP (Dixon 1999). The oldest archaeological evidence for skin boats is a wooden rib from a kayak-like vessel excavated at the 4000-year-old Saqqaq site, West Greenland. Two-thousand-year-old ivory models from the Ekven cemetery near East Cape, Siberia, represent both umiaks and kayaks. Birch bark miniatures of umiaks and kayaks as well as fragments of skin boat frames from the Miyowagh and Hillside sites on St. Lawrence Island in the Bering Strait are within the same date range. Skin boat parts were recorded at the Birnirk site in the vicinity of Point Barrow (500–1300 CE), at the Deering site in Kotzebue Sound (821–1200 CE), at the Qilalukan site on Baffin Island, and in cave sites on Kagamil and Kanaga Islands in the Aleutian chain (890–1667 CE). On Labrador, remains of kayak frames and paddles have been discovered in late prehistoric/early contact period graves at various sites. Skin boat frame finds have also been recorded in archaeological sites of both west and east Greenland (Gulløv 1997). All archaeological skin boat components have been found in terrestrial sites; no underwater remains have been discovered to date. The presence of boat fragments in house remains and middens indicates reuse of wooden components and suggests a ritualistic significance of skin watercraft. Ethnographic data show that fragments of both kayaks and umiaks were kept as amulets ensuring prosperity and long life. In Greenland, ivory line holders from old kayaks were worn as protective charms on amulet belts. Stem and stern posts were often taken from older, dilapidated vessels and used in the construction of new boats, thus transferring the expertise of the previous generation in both physical and metaphysical senses. Boat elements among grave finds may also indicate that skin boats were considered necessary in the afterlife of the deceased.

Although important, all these finds provide only fragmentary information about the constructional details of circumpolar skin boats. Intact skin boat assemblages are rare in the circumpolar archaeological record. About one third of a kayak frame with associated implements was discovered in 1921 in Washington Land, North Greenland. Found on a hill slope, 40 m. above the sea, the kayak had been put there for future use some time in sixteenth or seventeenth century. The Peary Land umiak, the oldest complete circumpolar skin boat known today from the archaeological record, was deposited in similar circumstances (Fig. 2). Discovered by a Danish expedition to Peary Land, northeast Greenland, in 1949, it dates to the fifteenth century CE (Petersen 1986). Iron fasteners and an oak timber indicate that the makers of the Peary Land umiak were in contact with the Norse. Contact with nonnative explorers, settlers, and whalers in the Arctic had significant impacts on many aspects of indigenous life, including watercraft. Shifts in technology and subsistence resulting from newly introduced materials and trading opportunities, as well as from the decline of human and whale populations, changed skin boat construction and use. Today only a handful of native communities in the circumpolar north maintain traditional skin boat building.

The historical exploration of the Arctic is a topic that has fascinated the public (especially the race for "firsts" in polar exploration and achievement). The history of Arctic exploration

Arctic Ocean and Bering Sea: Maritime Archaeology, Fig. 2 Skin boats

by European nations (essentially a maritime endeavor) has its roots in the sixteenth-century push for easier and more direct routes between Europe and Asia. Three routes were considered or attempted at various times: a route directly across the Arctic Ocean, the "Northwest Passage" through the Davis Strait and the Canadian Arctic Archipelago, and the "Northeast Passage" along the northern coasts of Scandinavia and Eurasia. Numerous expeditions, including those of Martin Frobisher (1576–1578), John Davis (1585), and William Baffin (1616), ventured into the eastern Arctic in search of routes across the top of North America (Delgado 1999). The Northeast Passage was also tried, for example, by Willem Barentsz in 1596. Others attempted to find the western terminus of the Northwest Passage by sailing through Bering Strait (i.e., James Cook, in 1778). Various traces of these expeditions, including remains of vessels, camps, and gravesites, have been investigated by archaeologists in the high Arctic.

The first attempt to find a sea route from Europe to Asia via the Northwest Passage was undertaken by Martin Frobisher in 1576–1578. Frobisher reached Baffin Bay and established a camp on Baffin Island, where the expedition prospected for gold. Frobisher's account is among the earliest written records of European-Inuit interaction. The Frobisher camp on Baffin Island has been excavated by joint Smithsonian Institution/Canadian Museum of Civilization project (the "Meta Incognita" project). The project also collected Inuit oral traditions relating to the Frobisher expedition (McGhee 2001).

Among the earliest attempts to sail the Northeast Passage was the voyage undertaken by Dutchman Willem Barentsz in 1596. Barentsz and his crew were forced to spend a winter on the northeastern tip of the island of Novaya Zemlya after their ship was crushed by ice in the Kara Sea (Fig. 3). Barentsz himself died during the trip, and the survivors among his crew returned to Amsterdam via Russia. The site of Barentsz's camp on Novaya Zemlya was apparently untouched for over 200 years but has been visited several times since then – initially by other mariners and finally by collectors and enthusiasts. A number of artifacts thus found their way into museum collections, mostly the Rijksmuseum in Amsterdam and the Arctic and Antarctic Museum in St. Petersburg. Most of the recovered objects pertain to shipboard life of the late sixteenth century, well-preserved by the cold climate. An archaeological survey of the site, undertaken in 1992 by a joint Dutch-Russian team, found little but wooden foundations of a house built of driftwood and ship's timbers by Barentsz and his crew (Hacquebord 1995).

Despite high costs and complicated logistics, underwater investigations have also been carried out in the Arctic. The first substantive underwater archaeology in the Arctic was a survey of the vessel *Maud*, a three-masted wooden schooner built in Asker, Norway, in 1917 for polar explorer Roald Amundsen. Amundsen, who had been the first to pass through the Northwest Passage in the sloop *Gjoa*, intended to reach the North Pole by freezing the ship in sea ice and drifting north. *Maud* was custom-built for his proposed Arctic research. Amundsen sailed from Norway in July of 1918, headed for the Northeast Passage. By mid-September of 1918, *Maud* was frozen in the

Arctic Ocean and Bering Sea: Maritime Archaeology, Fig. 3 Frobisher's camp on Baffin Island

ice in the Laptev Sea. When *Maud* finally broke free in late summer of 1919, she was able to sail for only 11 days before freezing in again for the winter, this time near the mouth of the Kolyma River. After breaking free in the summer of 1920, Amundsen and his crew were able to pass through Bering Strait and put into Nome, Alaska. *Maud* was thus the second vessel to navigate the Northeast Passage (after N.A. Nordenskjold's *Vega*), and Amundsen became the first to pass through both the Northeast and Northwest Passages. Amundsen made two more attempts to freeze *Maud* in pack ice and drift to the pole but was thwarted each time, and the project eventually ran out of funds. *Maud* was seized by creditors in Seattle in 1922 and sold at the auction to the Hudson's Bay Company. The new owners renamed the vessel *Baymaud* and sent her to resupply company outposts in the Western Arctic.

In late 1927 the vessel froze in the ice at Cambridge Bay (Victoria Island). Shortly thereafter a leak developed that required repair facilities not available in the Arctic, and the vessel sank at her moorings in 1930. An underwater site inspection undertaken in 1996 determined that while the lower hull was substantially sound, much of the upper structure had degraded, largely due to ice action. The weather deck, except at the bow, is nearly completely destroyed, and the upper hull sides have been significantly broken down (Delgado 1997) (Fig. 4). *Maud* is officially owned by the Norwegian town of Asker, which bought the wreck from the Hudson's Bay Company in 1990. In August 2016, a team from Asker refloated the vessel and plans to transport her to Norway on a custom-built barge to be restored and opened as a museum ship.

Among the most sought-after underwater targets in the Arctic are those connected with the voyage and attempted rescue of the Franklin Expedition. In May of 1845, British Royal Navy ships HMS *Erebus* and HMS *Terror*, under the command of Sir John Franklin, departed England on a much-publicized expedition in search of a viable Northwest Passage route from Europe to Asia. Both vessels were reinforced for operation in the ice, and both had already seen service in previous Arctic voyages. Provisions were taken for a voyage of up to 3 years duration, as the expedition expected to overwinter on their passage. Both ships became trapped in ice in late 1846 in the Canadian archipelago. Franklin himself died in 1847, along with at least 23 crew members. The remainder of the crew abandoned the vessels and attempted an overland escape. None survived, and the vessels were lost to the ice.

After several years with no word or sign of Franklin, rescue operations were mounted. In

Arctic Ocean and Bering Sea: Maritime Archaeology, Fig. 4 *Maud*, courtesy of Parks Canada

1850 the Royal Navy dispatched Captain Robert McClure with 66 men in HMS *Investigator*. McClure's orders were to round South America, pass through Bering Strait, and search for Franklin at the western end of the supposed Northwest Passage. Once in the western Arctic, McClure recognized Melville Island and realized that he had connected with parts of the archipelago previously reached from the east. After freezing in at Mercy Bay on Banks Island, the crew endured two harrowing winters before abandoning ship and sledging east. McClure and his crew were eventually rescued by other Royal Navy ships and upon their return to England were credited with the official discovery of the Northwest Passage.

The remains of HMS *Investigator* as well as the graves of three crew members were located in 2010 by a Parks Canada expedition. The wreck and associated debris field, initially located using side-scan sonar, rest in shallow water with the hull bottom buried in sediment. The hull appears to be substantially intact, although masts, rigging, and bulwarks have collapsed (likely as a consequence of damage from winter sea ice). Divers documented the vessel and recovered diagnostic artifacts and samples during a follow-up expedition in the summer of 2011 (Fig. 5). Parks Canada continued the search, and Franklin's vessel HMS *Erebus* was located in September 2014 in Queen Maud Gulf south of Victoria Island. A second breakthrough happened in September 2016 with the discovery of HMS *Terror* further north in Terror Bay. Both vessels rest upright on the bottom with significantly intact hulls. HMS *Terror* is

Arctic Ocean and Bering Sea: Maritime Archaeology, Fig. 5 Documenting the remains of HMS *Investigator*, courtesy of Parks Canada

particularly well-preserved, with bowsprit and portions of masts intact. The wrecks have been designated a Canadian National Historic Site due to the significance of Franklin's voyage and the importance of the two ships in the history of Arctic exploration and navigation as well as the establishment of Canadian sovereignty in the Arctic. Several other wrecks have been identified in Canadian Arctic waters (notably *Albany* and *Discovery* (1720) in Hudson's Bay and *Breadalbane* (1853) in Lancaster Sound). All three are in excellent condition, owing to depth or protective landforms which have protected them from serious damage from sea ice.

The whaling industry followed close on the heels of the polar explorers and also left remains for archaeology. Whalers were active in the Greenland and Barents Seas by the early seventeenth century, although commercial whaling in the Western Arctic began only in 1848. Over the next century, more than 2700 whaling voyages were made into Arctic waters at the cost of more than 150 ships lost and the near extinction of the bowhead whale (Bockstoce 1986). Occasionally entire whaling fleets would be lost. In 1871, for example, almost the entire Yankee whaling fleet was trapped in the ice in the Chukchi Sea. Thirty-one ships were crushed and destroyed in this single incident. A project focusing on the wrecks of 1871 fleet, undertaken in 2005–2008, documented extensive wreckage and artifacts washed up along the shore of northwestern Alaska (Fig. 6). However, diver surveys of side-scan sonar targets were unable to identify in situ remains.

Underwater investigations are somewhat rarer along the Russian coast of the Arctic Ocean, although numerous wrecks are known historically. One significant wreck, the steam vessel *Chelyuskin*, was located in 2006 in the Chukchi Sea and declared an archaeological site. The *Chelyuskin*, a freighter that sailed eastbound from Murmansk in 1933 to prove the viability of transiting the Northeast Passage, was caught in sea ice, crushed, and sank off the north coast of the Chukotka Peninsula. The vessel was located with sonar in 2006 and subsequently visited by divers; the ship's identity was confirmed by recovered pieces sent to the shipbuilder for authentication.

Whaling stations and other early "Arctic frontier resource" settlements on Svalbard have also been subjects of investigation, primarily by Dutch and Norwegian researchers. Svalbard (Spitsbergen) was discovered by Willem Barentsz in 1596 while searching for a Northeast Passage route to Asia. The Englishman Henry Hudson, while serving in the Dutch East India Company, reported many whales in the area, and commercial whaling started in 1611. Shore stations were established by English and Dutch whaling enterprises throughout the Svalbard

Arctic Ocean and Bering Sea: Maritime Archaeology, Fig. 6 Wreckage from the 1871 whaling fleet disaster, Wainwright, Alaska

archipelago as well as on Jan Mayen Island. Large furnaces were built to render whale blubber and wooden houses to lodge personnel. Although most whaling stations were abandoned by the early eighteenth century, mineral prospecting and mining camps soon took their place. Archaeological investigations of early camps and stations on Svalbard reflect not only the resource exploitation that followed the "Heroic Age of Polar Exploration" but also the subsequent geopolitical motives for establishing and maintaining settlements in the Arctic (Hacquebord and Avango 2009).

In contrast to the Arctic Ocean, maritime and underwater archaeology in the Bering Sea is in a state of complete infancy. Very few investigations have been attempted, despite the potential for significant cultural resources. One of the most significant projects to date is the joint Russian-Danish excavation of the campsite of Vitus Bering, on Bering Island. Bering and his crew shipwrecked on the island, at the western end of the Aleutian chain, in 1741 when returning from Alaska to Siberia. The investigation found ship's guns and timbers and identified the grave of Bering himself, who died and was buried during the sojourn on the island.

The only substantive underwater project conducted so far in the Bering Sea is the investigation of a side-wheel steamship, the *Eliza Anderson*, which wrecked at Dutch Harbor (Unalaska Island), in 1899. The vessel, in a worn and decrepit state, had been hastily outfitted to bring prospectors north from Seattle during the Klondike Gold Rush. The wreck was identified and surveyed in 2006 (Fig. 7).

Key Issues/Current Debates

There is currently no articulated comprehensive theory of Arctic maritime archaeology – partly due to gaps in scientific knowledge of the Arctic in general. Despite years of study by dedicated scientists, many basic questions remain to be answered. For example, we still do not have a definitive sea-level history for the Bering Strait or Arctic continental shelves, and bathymetry is patchy at best. The development of theoretical approaches to terrestrial archaeology in the Arctic has moved at a faster pace (i.e., Blankholm 2009; Westerdahl 2010), with several specialist journals dedicated to anthropological questions of the region. Regional maritime adaptations are regularly mentioned, although seldom analyzed in a circumpolar context. One reason for the lack of a more comprehensive theoretical approach may be due to a deficiency of truly multidisciplinary investigations; an accurate understanding of the full range of Arctic sites and formation processes requires the participation of not only a range of archaeological specialists but also marine and sedimentary geologists, oceanographers, cold-climate ecology scientists, and native tradition bearers.

Underwater site formation processes specifically may require a much broader assimilation of geophysical knowledge than heretofore assembled. For example, coastal erosion dynamics, vegetation regimes, and other ecological parameters are unlike those of any other region on earth and require investigation and definition. However, the most complex element of the Arctic maritime environment (and potentially significant for the preservation of submerged cultural remains) is the cyclical growth and movement of sea ice.

Ice formation and extent along Arctic coasts is seasonally variable. Ice formation generally begins in October and reaches an annual maximum in February or March; melting begins in May or June, and pack ice retreats during July and August. Most of the Arctic continental shelf is therefore under ice cover for 7–10 months each year. Pack ice is subject to immense wind fields, generated over a large area. The convergence of fields of moving pack ice (or pack ice impacting with shorefast ice) results in linear deformation features called pressure ridges. The intense pressures eventually build up ice masses both above the water's surface (ice sails) and below (ice keels). Ice gouging occurs where ice keels are driven into the seabed and are moved by the

Arctic Ocean and Bering Sea: Maritime Archaeology, Fig. 7 Remains of the *Eliza Anderson*, Dutch Harbor, Alaska

accumulated energies of the encompassing pack ice structure. The resulting furrows or tracks in the seafloor are described as ice gouges or ice scour (Wadhams 2000). Ice grounding and gouging is common in all Arctic coastal waters, from the sea's edge to considerable depths. Deep gouges tend to produce high flanking ridges to either side, creating combined vertical relief of up to 8 m. The highest gouge densities are in water between 20 and 40 m deep, as are maximum gouge depths. Gouges in water deeper than about 55 m are assumed by some researchers to be relict from periods of lower sea level, as modern ice features do not generally have keels extending beyond 60 m deep.

No comprehensive study has been undertaken regarding the potential effects of ice gouging on submerged archaeological sites and the

Arctic Ocean and Bering Sea: Maritime Archaeology, Fig. 8 Sea ice, courtesy of National Snow and Ice Data Center

consequent ramifications for site formation processes. Regarding the Chukchi Sea, the US Minerals Management Service has concluded that "shipwrecks are likely to have survived in the area, especially those that may be at a depth beyond intensive ice gouging" (Mineral Management Service (MMS) 2007). Archaeological investigations of historic period shipwrecks near Wainwright on the Alaskan Chukchi coast found considerable amounts of nineteenth-century wreckage in the beach and intertidal zones, presumably gouged from the seafloor and washed ashore. Investigations in the Canadian Arctic have similarly concluded that wrecks would survive only if protected from pack ice. When considering the potential for archaeological resources along the Arctic Ocean margins, the effects of the ocean's dynamic and complex environmental processes must be taken into account (Fig. 8).

International Perspectives

Since the earliest European attempts to find northern sea routes to Asia and claim Arctic lands, the region has been the focus of geopolitical maneuvering and intrigue. The situation has only intensified as climate change opens Arctic waters and resource exploration increases. While there is a regular high-level intergovernmental forum of Arctic nations (the Arctic Council), many issues remain to be resolved. Maritime borders are unsettled or in dispute. As of 2016 not a single Arctic nation had ratified the United Nations Convention on the Protection of the Underwater Cultural Heritage (and several were actively opposed to the convention). International collaboration on scientific projects is common in the Arctic, but it remains to be seen whether such cooperation will be extended in the future to underwater archaeological investigations.

Future Directions

Archaeology in the Arctic Ocean faces two major interrelated sets of challenges in the near future: climate change and human impacts. As described in an article by Hans Peter Blankholm (2009), much recent concern and attention has been focused on environmental and ecological implications of climate change, while culture-historical issues have been relatively neglected. However, archaeological resources, both terrestrial and submerged, will undoubtedly be affected by changes now occurring in the Arctic.

The warming climate is resulting in pronounced reductions in sea ice, seasonal snow,

permafrost, and glacial features, with a corresponding shift in landscape processes. What does this mean for archaeological resources in the affected areas? Continuing widespread loss of discontinuous permafrost and increase in the active layer of remaining permafrost will trigger erosion and subsidence of ice-rich landscapes and change local and regional hydrologic processes. Coastlines will be increasingly exposed to wave action and storm surge. Direct impacts from coastal erosion as well as the loss of stable preservation (frozen site matrices) will be varying degrees of resource exposure, degradation, and destruction of buried/frozen cultural material. The effects on submerged archaeological sites are less clear, although reduced sea ice may result in reduced potential for damage from ice scour.

The other major factor likely to impact Arctic archaeological resources (especially in a submerged environment) is a dramatically increased human presence in the region. Approximately four million people currently live in the Arctic. Increased accessibility and intensified resource exploitation will likely bring larger number of people into the far north. Oil and gas drilling on Arctic continental shelves is already intensifying in Alaska's Chukchi and Beaufort Seas, Norway's Barents Sea, and elsewhere. Impacts to submerged archaeological sites are possible from extraction and transportation facilities, pipelines, and related infrastructure. Reduced sea ice will create opportunities for increased open-water transportation (especially cargo shipping but also cruise tourism) (Nuttall and Callaghan 2000). As the Arctic enters this uncertain phase, protection and responsible investigation of the region's cultural heritage is a key concern.

Argentina: Maritime Archaeology

Dolores Elkin
Consejo Nacional de Investigaciones Científicas y Técnicas and Instituto Nacional de Antropología y Pensamiento Latinoamericano, Buenos Aires, Argentina

Introduction

Despite its long-standing tradition in archaeology and its vast maritime littoral and other waterways, the study of the relationship between humans and water through material remains has not had much development in Argentina.

The traditional focus has been in pre-Hispanic societies, either nomadic or sedentary, and almost exclusively from a land perspective. The few cases when water was considered within the cultural system under study were usually triggered by the presence of artifacts (like harpoons or other fishing devices) or ecofacts (such as fish, shellfish, or sea mammals remains) in the archaeological record. Until recently topics such as navigation and watercrafts per se, whether prehistoric or more recent, have been almost absent in the Argentinean archaeological research projects, let alone venturing into the water to study submerged archaeological remains of any sort.

Since the mid-1990s, however, the fields of maritime and underwater archaeology have been steadily growing, leading to a number of research projects and various other activities dealing with the country's underwater cultural heritage.

Definition

As the discipline of maritime archaeology continues to develop, so does its definition and the debate on the various topics of study it can comprise (Catsambis et al. 2011). In general terms, however, it could be defined as the study, through material remains, of past human cultures in their relation with the sea and occasionally with inland waters. Typical examples of the latter have to do with seafaring, given that oceans, rivers, and lakes are frequently connected and are navigated without distinction.

It is in that broad sense that the concept of maritime archaeology is used in this entry. Besides, although ships are not the only subjects of study, they were chosen to be the focus here not only because of their direct association with water but also because they are good representatives of maritime archaeology in Argentina.

Historical Background

Prior to the development of maritime and underwater archaeology with scientific standards, there had been various instances in which submerged archaeological remains were dealt with (see Elkin 2002; Ciarlo 2008). In the first decades of the twentieth century, they mostly had to do with isolated finds of shipwreck elements which ended up in museum or private collections, in most cases lacking contextual information.

By the 1970s archaeologist Jorge Fernández became involved in the extraction of a wooden canoe from a lake in Patagonia by guiding from the surface the work performed by professional divers and by later describing and interpreting the find (Fernández 1978).

The 1980s was characterized by several activities conducted by an ICOMOS-Argentina working group, mainly comprised by architects-divers, who had the initiative of building capacity in underwater archaeology techniques (see Elkin 2002). The main project in which this group became involved was the survey of the British sloop of war HMS *Swift*, sank in Puerto Deseado – currently Santa Cruz Province – in 1770, and which had been discovered by local divers in the early 1980s. The work was focused on the in situ recording of the hull structure as well as the excavation of some artifacts (Murray 1993; García Cano 1998).

In the early 1990s, a nonprofit organization called Fundación Albenga, directed by Architect J. García Cano, continued to work at the *Swift* site undertaking nonintrusive surveys (García Cano 1996).

The mid-1990s represents a major turning point in the discipline, with the simultaneous birth of two research teams in which archaeologists-divers played a leading role. One of the teams, known as PROAS for the acronym of *Programa de Arqueología Subacuática*, is based at the National Institute of Anthropology in Buenos Aires, under the direction of this author. The other one is based at the National University of Rosario (Santa Fe Province), under the direction of Mónica Valentini. Both groups have been very active since then – sometimes working in partnership with other institutions – and they usually involve specialists from other fields who contribute to the interdisciplinary aspects of the projects. Additionally, both teams have not only been conducting archaeological research but also implementing many initiatives related to raising awareness on the protection of underwater cultural heritage and contributing to capacity building at different levels (Elkin 2003; Valentini 2003).

Key Issues

This section presents the main ongoing or recent archaeological projects in maritime archaeology for which published data is already available. Figure 1 shows the geographic location of each of the case studies.

Argentina: Maritime Archaeology, Fig. 1 Map of Argentina with the location of the areas, sites, and projects mentioned in this entry. *a* Nahuel Huapi Lake, *b* Zencity wrecksite, *c* Reta wrecksite, *d* Valdés Peninsula, *e* HMS *Swift* wrecksite, *f Hoorn* wrecksite, *g* Monte León National Park, and *h* Atlantic coast of Tierra del Fuego

Studies on Navigation in Patagonian Lakes

The ethnographic and historical record of the Patagonian lakes, rivers, and maritime shorelines (on both sides of the Andes) provides descriptions on three main types of canoes made of local tree species which were used at the time of contact with European explorers, missionaries, and settlers. One was the *dalca*, made of

sawn wooden planks and which could be dismantled to be transported on land. Another type was made of sawn bark planks and was mostly used by the Yamanas and Alakaluf in the southernmost tip of the continent; these groups mainly travelled along maritime waterways connecting the numerous islands and fjords around Tierra del Fuego. The third type of canoe, called *huampo* or *huampu* in some regions, was dug out from a single tree trunk with the aid of fire and initially using lithic and occasionally shell-made tools, later replaced by metal ones.

As stated earlier, back in the 1970s, archaeologist Jorge Fernandez was the first one to address the study of a wooden canoe. It was dug out from a single trunk of a beech tree and was recovered from the Nahuel Huapi Lake close to the city of Bariloche. Since, aside from the use of fire, there was evidence of the use of metal tools in its manufacture and traces of metal corrosion, it was chronologically attributed to a period between the mid-seventeenth and late nineteenth century (Fernández 1978).

Ferncndez continued to study and compare various other canoes of this type found by different people in the Andean lakes of Northwest Patagonia, also taking into account historical, ethnographic, and geographic information in his research. On that basis, combined with early archaeological evidence in an island in the Nahuel Huapi Lake which cannot be reached without some watercraft device, he concludes that the seafaring tradition in the region (including the rivers and lakes on the western side of the Andes) must date from prehistoric times (Fernández 1997).

The topic of the Patagonian lake district seafaring has been addressed more recently by other researchers, in Argentina especially by Romina Braicovich (Braicovich 2006; Braicovich and Caracotche 2008). She studied a number of dugout canoes found in the Nahuel Huapi Lake, including some of the ones previously studied by Fernández (Fig. 2). She concludes that all of them probably belonged to local people who lived in the area between the late 1800 and the early decades of 1900 (Braicovich 2004 in Braicovich 2006: 62–3). However, like Fernandez and like Hajduk (Hajduk 1997 in Hajduk and Valentini 2002), she also points out the existence of rock paintings and radiocarbon datings of c. 2000 BP in Victoria Island in the Nahuel Huapi Lake, which suggest that the local aboriginal groups had been navigating in that area since much earlier times (Braicovich 2006: 55–6).

Argentina: Maritime Archaeology, Fig. 2 Dugout canoe known as *Canoa Correntoso* extracted in 1968 from the Nahuel Huapi Lake, close to the town of Villa La Angostura. (Photograph from the Historical Museum Archive, Villa La Angostura, Neuquén)

Far away from the Patagonian lake district, similar indirect evidence of seafaring comes from Isla de los Estados (Staten Island), east of Tierra del Fuego in the South Atlantic Ocean. The island has an archaeological record which goes back to 2700 BP, although no boat remains from those times were found yet (Borrero 2001).

Studies on Shipwreck Sites in the Río de la Plata and the Atlantic Ocean Coast

The Zencity Shipwreck

This site consists of a wooden ship found in 2008 in the city of Buenos Aires, in the riverfront district of Puerto Madero, a place where many landfills have taken place particularly after a harbor was built in the late nineteenth century.

The find took place during the excavations for an urban development construction complex called Zencity. The recording and excavation of the site was therefore conducted as rescue archaeology within a period of 90 days, as a Project of the Dirección de Patrimonio e Instituto Histórico of the Ministry of Culture of the City of Buenos Aires. A recent publication by M. Valentini and J. García Cano (Valentini and Cano 2011) provides a summary of the main results achieved so far in the archaeological research of this site.

The Zencity wreck was a medium-sized (no more than 30 m of deck length) vessel, with a complete hold from bow to stern, and a design which optimized the use of stowage space. The in situ recording of hull and artifacts was done with the aid of the computer software PhotoModeler, which allows a 2D and 3D digital reconstruction.

The combination of the constructive characteristics of the ship and the analysis of the archaeological remains indicate it was a Spanish merchant ship which arrived to the city of Buenos Aires in the second half of the eighteenth century. Preliminary dendrochronological dating of various oak timbers places the ship's construction in the mid-eighteenth century.

The hull was made of European oak, which suggests the vessel was built in the northern region of Spain, where oak forests were available. This northern Spain shipbuilding tradition, known as Cantabrian tradition, made an intensive use of oak trees and produced vessels which were highly sought after due to their resistance, durability, and strength.

Regarding the artifact collection, the most abundant items are ceramic containers known as *botijas* (olive jars), which were found in the stowage sectors of the ship's hold (Fig. 3). Over 200 *botijas* of different sizes were found, both complete and fragmented. They all have a cone-shaped base and lack handles, a practical shape for sea transportation. There is evidence of wheel throwing for the manufacture of the body, while the neck could be finished by hand. Some of these *botijas* were found sealed with a stopper in place and with olive seeds inside.

The *botijas* from the Zencity wreck represent one of the largest collections in Argentina of this type of container. It was used in the oceanic trade

Argentina: Maritime Archaeology, Fig. 3 Some of the botijas found in the Zencity wreck. (Photograph courtesy of Mónica P. Valentini and Javier García Cano)

between Spain and the port of Buenos Aires in colonial times and played an essential role in the transportation and storage of products for this remote region of the Spanish empire.

Other type of artifacts found in the site includes metal fittings such as wrought iron tacks, nails, and bolts, all of them consistent with the Spanish manufacture techniques reported for the period, as well as different types of smoking clay pipes, most of them fragmented. The rest of the collection comprises various metal, wood, and ceramic artifacts, as well as animal bone remains.

The hull structure of the ship was reburied in a nearby location that provides similar environmental conditions to the ones which had preserved the ship for so long. It was then covered with various layers of geotextiles and other materials which contribute to its preservation. The reburial site is monitored by constant soundings in precise locations which allow the control of variables such as humidity, salts, oxygen, and acidity.

As it is the case with other former European maritime powers, the study of merchant ships has been often neglected in comparison with warships built by or for the state, and the Zencity wreck presents an excellent opportunity to shed light on the topic.

The Reta Shipwreck

Reta is a seaside resort located nearly 600 km south of the city of Buenos Aires. Due to the presence of an unidentified wooden wreck located on the beach above the intertidal zone, in 2002 a joint team from the University of Rosario and the *Fundación Albenga* conducted a survey and excavation of the site (Fig. 4) that revealed a nearly 30-m-long structure. Subsequent metallographic and chemical studies made on samples of plates and tacks from the metal sheathing showed that the first consisted of a copper-zinc alloy (60% and 40%, respectively), which was patented by Muntz in 1832 and soon became of general use (Lorusso et al. 2003). On the basis of the survey and research, the authors have concluded that the ship very probably dates from the late nineteenth century (Valentini 2003).

The Peninsula Valdés Project

The Valdés Peninsula in Chubut Province is a UNESCO World Natural Heritage site, featuring a spectacular marine wildlife. The nearby city of Puerto Madryn, gateway to the peninsula, is also the main scuba-diving destination in Argentina, offering a number of activities including shipwreck diving.

Argentina: Maritime Archaeology, Fig. 4 Survey of the Reta wrecksite. (Photograph courtesy of Mónica P. Valentini and Javier García Cano)

The context summarized above seemed to provide a good platform for developing public awareness and public outreach initiatives. With that general goal in mind, the PROAS team started a pilot project in the Madryn-Valdés area which comprised a preliminary survey of existing shipwrecks (both historic and modern), followed by a more detailed in situ recording and investigation of selected sites. In the long term, the Madryn-Valdés Project is expected to contribute to the development of cultural tourism in the area.

The first field seasons and archival research conducted in the initial stages of the project revealed the presence of some 30 shipwrecks and ship-related sites in the area, 6 of which were selected on the basis of their historical, archaeological, and/or touristic significance (Elkin and Murray 2008). The site that has been studied more thoroughly to date will be described below.

Bahía Galenses 2 (BG2) consists of the remains of an unidentified wooden vessel located in one of the Southern beaches of Puerto Madryn city. Lying in the intertidal zone, it consists of a 28-m-long section of a hull that was becoming increasingly exposed to the elements. A preliminary nonintrusive survey suggested that the original vessel may have been built in the eighteenth or nineteenth century.

With the goal of conducting a more specific assessment of the cultural and chronological affiliation of this wreck, archaeological field seasons were carried out between 2006 and 2016 (Fig. 5). The work consisted of the following (Elkin et al. 2015; Murray et al. 2009):

Completing a site plan of the exposed structure.

Digging several test pits around the perimeter in order to better understand the nature and position of the structure.

Excavating three cross-section trenches in the middle and end sectors of the site (considered potentially diagnostic).

Surveying diagnostic features of the structure.

Taking samples of the wooden structure, metal fittings, and any other material that could contribute to its understanding.

Argentina: Maritime Archaeology, Fig. 5 Recording of structural components of BG2 site

Excavating the surroundings of the main site, where parts of a ship structure and an apparent cauldron were located.

The archaeological research revealed that the structure is part of a wooden-sailing ship, probably a merchant or fishing vessel of 300–500 t burden, which could have sank due to a fire possibly around the mid-nineteenth century. Botanical taxonomic analysis indicated that European and American wood were used in the construction. Interestingly, the archaeological evidence seems to coincide with historical documentation that indicates the presence of a shipwreck in the area by the time the first Welsh settlers arrived, as well as with the reported salvage of wood from such wreck by the Welsh (Coronato 1997). This inference is based on the fact that some of the buried timbers show evidence of non-recent cutting with an axe or a similar sharp-edge tool. Further botanical and chemical analyses will be conducted for BG2 seeking a better understanding of this wrecksite.

The HMS Swift

HMS *Swift* was a British sloop of war lost in 1770 after striking a sunken rock in the Deseado estuary, Santa Cruz Province, Southern Argentina.

The site was discovered in 1982 by local divers from Puerto Deseado at a depth of 18 m within what is nowadays the commercial harbor area. After several interventions in the site during the 1980s and early 1990s – mainly by the aforementioned ICOMOS-Argentina working group – since 1998 the archaeological research has been conducted by the underwater archaeology team of the National Institute of Anthropology.

The *Swift* is characterized by its outstanding preservation, constituting one of the most complete archaeological examples of an eighteenth-century Royal Navy sloop worldwide. This is mainly due to the anaerobic conditions created by the fine-grained sediment that covers the archaeological remains. It is estimated that about 60% of the original wooden hull structure is preserved and the archaeological assemblage comprises a great variety of artifacts made of ceramic, metal, glass, wood, stone, and bone. Other organic remains have been found too, mostly associated with clothing, food, and rigging. During a field season conducted in 2005–2006, a complete human skeleton was unexpectedly discovered.

The general goal of the project was to record in situ as much of the hull structure as possible and to excavate selected sectors of the ship in order to address the main research themes under study: ship construction, contemporary technologies, relationship between material culture and status, diet, site formation processes, and, due to the finding of human remains, health and other bioanthropological topics. Along 15 field seasons conducted to date, significant progress has been accomplished (Elkin et al. 2007, 2011).

Regarding the study of the ship construction, the main results indicate that significant alterations have taken place in the rigging and the decks layout, probably with the purpose of adapting the vessel to transoceanic sailing and other aspects of its service.

The technological characteristics of the ship itself and the artifact collection is, in general terms, consistent with what was standard for the cultural and chronological period under study.

As for the relationship between material culture and status, despite the presence of Chinese export porcelain and other high-quality and elaborate artifacts associated with the officers, some other items they used, including furniture and personal belongings, were made quite coarsely or lacking decorative traits. It is worth noting, nonetheless, that some of the furniture was provided by the British Admiralty and would not necessarily reflect the officers' choice. Regarding the ordinary seamen, to date only a few artifacts can be associated to them. These mainly consist of leather shoes, wooden bowls or parts of them, and glass beer-type bottles.

The food remains found in the site allowed concluding that the diet was quite varied, including fruit and vegetables – although not necessarily fresh – and complemented with local resources such as penguin eggs.

The study of site formation processes revealed a significant attack of marine borers both in some sectors of the main deck of the ship and in some of the artifacts, the latter located at different depths within the sediment matrix. The characteristics of the tunnels correspond to those made by molluscs, although no living or dead specimens which could allow their precise taxonomic identification were found.

The discovery of human remains in the site opened a new line of research within the project, initially based on the hypothesis that they corresponded to one of the three men reported as dead after the sinking, two of which were private marines.

The bones correspond to a male individual, around 25 years of age (range 17–34), measuring 1.67 m of height, probably right handed, and with an overall good health. In turn, the analyses of several elements which were found in association with the skeleton such as buttons, buckles, and fragments of leather corresponding to spatterdashes indicated that the person found in the site must have been wearing a uniform of some sort. Additionally, chemical studies conducted on traces of cloth attached to the upper body revealed it was red wool like the jackets which were worn only by the marines.

On a parallel research strand, DNA was extracted from selected bone samples taken from the archaeological skeleton. However, the fact that it is mitochondrial DNA – only transmitted by females – poses considerable challenges in the tracking down of relatives. Nonetheless, genealogical studies will be conducted in an attempt to identify the skeleton found in the *Swift* site at an individual level.

The 2010 field season at the *Swift* allowed investigating the topic of health on board by means of excavating a compartmented wooden chest full of what seemed to be medicinal items. Most of the containers correspond to pharmaceutical vials of the time, an interpretation which is already being supported by the analyses of some of the contents (Edwards and Maier 2011 in Elkin et al. 2011). These include substances such as pure mercury – believed to cure syphilis – and extracts of natural substances which could have been used for treating various ailments.

The Hoorn

In the early seventeenth century, Dutch merchants Jacob Le Maire and Willem C. Schouten engaged in a major sea voyage in search of a new passage to the Spice Islands. Shortly after crossing the Atlantic Ocean, the two vessels of the expedition entered into the Deseado estuary, and one of them, the *Hoorn*, accidentally caught fire and was lost while being careened on the shore in 1615.

A bilateral research project conducted by Argentinean and Dutch archaeologists (Damián Vainstub and Cristian Murray, from PROAS-Argentina, and Martijn Manders, from the National Service for Archaeological Heritage (ROB) of Holland) began in 2003 with the goal of locating and studying the remains of the vessel. The combination of a thorough review of various historical sources, an analysis of the coastal geomorphology, and some surveys along selected coastal zones allowed to locate the wrecksite. A few elements from the *Hoorn* were found on an intertidal pebble beach, although no structural remains of the ship could be seen. The main archaeological evidence comprised allochthonous rocks interpreted as ballast materials,

Argentina: Maritime Archaeology, Fig. 6 Analyzing the images of the side-scan sonar survey in the Hoorn project

various ceramic shards from the chronological and cultural context under study, and melted metallic fragments made of pewter and brass alloys, silver, and lead (some of which contained carbon fragments and seeds inside), which surely resulted from the fire on board (Murrray et al. 2007).

Subsequent side-scan sonar and magnetometer (Fig. 6) surveys, combined with selected scuba diving, focused on the adjacent seabed. This allowed the location of ferrous concretions which were later X-rayed, revealing the impressions of corroded iron artifacts such as nails, fittings, and bolts (Murrray et al. 2007, 2008).

No hull remains were found underwater or on land, probably due to the combination of the dynamic environment of the location and to salvage activities that must have taken place along several centuries.

Despite the relatively few archaeological remains from the *Hoorn* that have survived, it is the earliest identified shipwreck site in Argentina to date.

The Monte León Project

Monte León is a national park located in Santa Cruz Province, being the first one in the country's national parks system to include an ocean coastline and which stretches along some 40 km.

Although the entire Patagonian coast has been intensively explored – and eventually colonized –

from the sixteenth century onward, from the maritime history point of view, the central coast of Santa Cruz Province, where the Park is located, has an additional appeal: one of the vessels of Hernando de Magallanes, the Nao *Santiago*, was lost in the area in 1520, in the context of the renowned voyage around the world carried out between CE 1519 and 1522.

Partly due to this situation, which causes periodical amateur expeditions in seek of the famous wreck, but also with the more general goal of assessing the maritime heritage of the park, the PROAS team was requested to conduct a coastal field survey.

After an initial compilation of various sources which could shed light on the potential nature and location of archaeological remains related to seafaring in the region (including, of course, historical documents related to Magellan's expedition), two seasons were carried out in the park in 2006 and 2007, respectively.

The archaeological surveys were conducted along the intertidal zone, which not only was the most reasonable one for a baseline study but also because it was the one in which the various documents analyzed in relation to Magellan's expedition suggested that the *Santiago* was lost.

During both field trips, interviews with local people were conducted, and the recording of materials previously extracted from the area took place.

Although no remains were found of the *Santiago* (nor any vessel from the period), the archaeological survey of the coast of the Monte León National Park revealed the presence of at least two wooden shipwrecks. Both of these probably date from the second half of the nineteenth century, both are between 300 and 500 t burden, and one of them was built with European woods (Elkin 2011). It is expected that future research will allow testing some hypotheses regarding which specific vessels the archaeological remains belong to.

The Atlantic Coast of Tierra del Fuego Project

The archipelago of Tierra del Fuego and surrounding islands is located at the southernmost part of the Americas, and it is characterized by quite challenging navigation conditions. Prior to the opening of the Panama Canal in 1914, seafaring between the Atlantic and Pacific oceans required facing the rough waters of the region, leaving behind a large number of shipwrecks which are reported in various historical accounts.

In 2010 the *Museo del Fin del Mundo*, based in the city of Ushuaia, sets forth an archaeological project which includes the goal of locating remains of historical shipwrecks along the Atlantic coast of Tierra del Fuego island and conducting preliminary surveys on them. The first field season allowed to locate around 20 sites consisting of various types of shipwreck remains (Vázquez et al. 2010), and further surveys allowed a better understanding of the sites, the methodological approaches which appeared to be more effective in them, and their site formation processes (Elkin et al. 2017).

Future Directions

Along two decades of development, and with the aid of more experienced countries that have provided theoretical and practical training in maritime and underwater archaeology, Argentina is now quite well positioned in the field. Little by little the specialty is also attracting younger generations of students and graduates who engage in various activities such as courses, underwater and coastal work, and even in the production of university-level dissertations. Since 2016 the Department of Anthropology of the School of Philosophy and Letters of the University of Buenos Aires has started to offer an undergraduate level regular academic course in maritime or underwater archaeology.

The awareness regarding the importance and fragility of the underwater cultural heritage is also increasing within the sport diving community and the general public. The Argentinean professionals who work in maritime archaeology periodically carry out courses, lectures, mass media interviews, and other activities that contribute to that goal.

Regrettably, however, the human and financial resources not only in Argentina but in the whole South American region are still too scarce to implement anything but small-scale projects, even without excavation. Additionally, the field of conservation of waterlogged materials is almost inexistent.

As for management, the national legislation provides a blanket protection for all underwater archaeological sites of at least 100 years of age, but due to the aforementioned scarcity of resources, the effective protection and management of such heritage is still far from becoming a reality. In the meantime, a central goal at the national government level is the development of a register of underwater cultural heritage sites, which will eventually be integrated into an archaeological register hosted at the National Institute of Anthropology. So far the data – obtained in the vast majority from written and oral sources – has been compiled either in the form of simple spreadsheets or in a database in access format. The next step will consist of starting to use GIS tools that can provide cross-references between the data and specific geographical locations. In turn, this will allow defining areas with greater or lesser potential for underwater cultural heritage and optimizing the planning and implementation of archaeological surveys. The use of remote sensing techniques, still very seldom used in the country, would certainly contribute to achieve such goal.

Last but not least, in 2010 Argentina ratified the UNESCO Convention on Underwater Cultural Heritage. Such a significant political step, combined with the existing basis of professionals and avocationals engaged in maritime and underwater archaeology, leads to believe that the field will continue to grow and so will the knowledge of the maritime past of the nation.

Argentine Society of Anthropology

Mónica Alejandra Berón
IDECU, UBA, Buenos Aires, Argentina

The Argentine Society of Anthropology (SAA) was founded on April 24, 1936 by a group of pioneers dedicated to Anthropology and other related disciplines. The founding meeting was chaired by the then director of the Ethnographic and Anthropological Museum (Faculty of Philosophy and Letters of the University of Buenos Aires), Félix F. Outes. Francisco de Aparicio, Eduardo Casanova, José Imbelloni, Fernando Márquez Miranda, Enrique Palavecino, Felix Outes, and Milcíades Vignati were also present. The Society has had a long and fruitful life, although with the ups and downs of the entities of this nature, inevitably linked to the political and economic swings of the country. Today it has dedicated more than eight decades to the national anthropological discipline (http://www.saantropologia.com.ar).

The mission of the Argentine Society of Anthropology, as expressed in Art. 2 of its Statutes, is "to promote anthropological research in the country and coordinate the efforts of those who today dedicate themselves to studies of this nature." From the beginning, the Society brought together different specialists in the anthropological sciences, although archaeologists predominated, a situation that remains unchanged to this day. In its beginnings, those interested in these sciences also joined, which markedly enlarged the list of associates. Since 1936, a Board of Directors was established, made up of a president and several members, whose positions were adjusted along the time, according to the needs (Secretary, Treasurer, titular and alternate Vocal Members, Account Reviewers). In a meeting held on May 4, 1936, it was stipulated to continue with the meetings at the headquarters of the Anthropological and Ethnographic Museum (today the "Juan B. Ambrosetti" Ethnographic Museum) which is situated since 1927 in the building built in the nineteenth century by the architect Benoit, located in Moreno 350 of the City of Buenos Aires (Pérez Gollán and Dujovne 1996).

In 1938 appeared the volume 1 of the journal *Relaciones of the Argentine Society of Anthropology*, corresponding to the year 1937, directed by Francisco de Aparicio and conformed by 17 articles and a memory that reviewed the activities of the Society. This volume was followed by three others in 1940, 1942, and 1944. Shortly after, a printed bulletin "Bulletin of the Argentine Society of Anthropology" was inaugurated, which since 1942 served as a communication channel with the partners and which is currently continuing on the Internet. Another outstanding task carried out by the Society was the completion of the Anthropology Weeks, annual meetings of specialists that took place in different cities of the interior and in the capital itself (Podestá 2007).

The rising rhythm of the Society was interrupted in 1945, and it was deprived of the subsidy it received. This fact was going to inaugurate a series of ups and downs in the history of the Society that printed a state of uncertainty to our association. Beginning in the 1970s, new figures, such as those of Eduardo M. Cigliano and Carlos J. Gradin, gave renewed strength and character to the Society. Gradin was able to finalize the edition of 16 volumes of Relaciones journal, through a great personal dedication and with the collaboration of CONICET that subsidized the printing of the magazine for many years (Podestá 2007). The journal *Relaciones of the Argentine Society of Anthropology* is a publication with referees of national and international prestige. It is dedicated to publishing unpublished articles, notes, and commentaries based on research that provide original information about the various specialties of anthropology (archeology, sociocultural anthropology, bioanthropology, ethnohistory, linguistics, and related disciplines), which provide relevant and useful conclusions for the scientific community. In accordance with national and international standards, it has renewed its inclusion in the Basic Nucleus of Argentine Scientific Journals of

CONICET, which constitutes a guarantee of the excellence of the publication. For more than a decade, the publication has been subsidized by the National Endowment for the Arts (FNA). In addition, the contribution of the partners was always the main economic support of the publication, as it continues to be today. Currently 42 volumes have been published, every 6 months (No. 1 and 2) in digital format, and annually, both together in printed format. The SAA currently gathers as members nearly 550 professionals and students of the country related to all specialties of Anthropology.

Currently the official headquarters of the SAA is located in the Ethnographic Museum "J. B. Ambrosetti" of the Faculty of Philosophy and Letters of the UBA. The SAA maintains relationships with other national institutions of the discipline such as the Association of Professional Archaeologists of Argentina (AAPRA), the Graduate School in Anthropology (CGA), and the Association of Professionals in Archeology of Tucumán.

The SAA develops an intense editorial work. Since 1999, it has been publishing Doctoral Theses, Bachelor Thesis, Publications, and Co-editions collections, which now total 42 titles. Recently a new series called Divulgation was inaugurated, which aims to reach a nonprofessional audience.

In addition, the SAA participates in the organization of scientific events. It collaborates forming the permanent organizing committee of the Jornadas de Arqueología de la Patagonia (since 1993) and of the Archeology Congress of the Argentine Pampean Region (since 1998). It organizes conferences and courses of diffusion and scientific training on anthropological or related topics, as well as book presentations, and events of a scientific nature. It represents the Argentinean anthropological community at a national and international level.

The SAA is a member of the International Federation of Rock Art Organizations (IFRAO) through its Rock Art Research Committee (CIAR-SAA), representing Argentina internationally in topics related to the research and dissemination of Argentine rock art. It has an updated library specialized in Anthropology formed through the national and international inter-institutional exchange and a documentary file gathered from the first years of its history. It is part of the Permanent Meeting of Scientific Associations of Argentina (EPAC). It also highlights researchers of national anthropological work for their scientific merits, naming them Honorary Partners. It annually holds an Ordinary General Assembly in which the members are concerned with the balance and accounting report, the new printed volume of Relaciones, and the books published by any of their editorial series. Issues of relevance to the SAA are discussed, the amounts of the annual quota are fixed, and consensus decisions are taken by vote. Every 2 years the Board of Directors is renewed by presenting lists and the vote of the members present in the Assembly. It is also an opportunity for meeting and celebration between partners.

Armed Conflict and Archaeology: Ethical Issues

Valerie Higgins
The American University of Rome, Rome, Italy

Introduction

Confronting the ethical issues of protecting the archaeological record during armed conflicts has arguably never been more challenging than during the first quarter of the twenty-first century. The use of heritage as a propaganda tool by terrorists and non-state actors has cut across more than a half

century of painstaking international legislation and lobbying which aimed at barricading cultural heritage behind a protective legal cordon that would be respected by all parties during a war. Before the Internet, 24 hour news, and social media, it was relatively easy for archaeologists to remain cocooned within academia or within professional archaeology units preoccupied with their own ethical struggles with developers and funding. Now archaeologists are forced daily to question their own role in armed conflict. Images of the destruction of artifacts in Mosul Museum, a (photoshopped) mushroom cloud above the Temple of Baalshamin at Palmyra and the murder of Dr. Khaled al-Asaad, Head of Antiquities at Palmyra, have stripped away any vestiges of doubt that archaeology can be elevated above the horrors of war. With this new accessibility to information come new ethical challenges to be faced.

Definition

The rapidly changing nature of warfare and a volatile geopolitical situation have presented archaeologists with new ethical challenges. At the time of writing, the events of Syria and Iraq dominate world news; therefore much of this work relates directly to these armed conflicts. However, some issues, such as looting, are of more universal application.

Key Issues/Current Debates/Future Directions/Examples

In the aftermath of the destruction of World War II, there was a concerted effort in the international community to find ways to protect cultural heritage during future wars. In November 1945 UNESCO was born, and most of its first decade was devoted to the formulation of the 1954 Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict. This called on all parties in a conflict to respect their own cultural heritage and that of the enemy. Getting individual countries to sign up to the convention and enact it as a part of their national law has been a lengthy process and is still ongoing. As of the summer of 2018, 133 states parties have, in one form or another, adopted the Convention.

In areas other than legislation, UNESCO worked to cultivate an international response in line with the founders' intentions of using cultural heritage to unite nations, rather than divide them. In the 1960s, in an unprecedented act of collaboration, an international team worked together to relocate and excavate 23 temples in upper Egypt, ahead of their inundation by the waters of the newly built Aswan Dam; in 1966 specialists from many nations assisted Florence and Venice in emergency conservation works after their priceless treasures were caught in floods; in 1970 a convention was passed to regulate the international trafficking of cultural property, and in 1972 the convention that led to the setting up of the World Heritage List was launched, official recognition that some heritage is so valuable that we all have an interest in it.

The first indications that these measures not only might be insufficient to safeguard heritage during conflict but could themselves become the agents of its destruction surfaced during the Balkans' conflicts of the 1990s. As Yugoslavia broke up, the official lists of heritage sites, compiled in order to ensure their protection, instead were used to pick targets for attacks on rival groups (Wasalek 2015: 53). The situation demonstrated the Achilles' heel of all the provisions that had been built up since World War II. The measures passed by UNESCO and the UN, and the heritage laws enacted through individual states parties, relied entirely on the premise that conflicts would be fought between nation states who would, nominally at least, conform to international law. There was no strategy for dealing with conflicts where the participants were outside the structure of government and who had no interest in, or intention of, obeying the rules. The issue became apparent during the Balkans' conflict, but ultimately was not fully addressed before political developments overtook these considerations. Ex-Yugoslavia gradually devolved into a series of smaller states, and the fighting died out. Eventually the non-state forces became part of a series of new states. Lessons learned resulted in an additional protocol, which was added to the Hague Convention in 1999 as an attempt to strengthen its effectiveness

in conditions of civil war. A decade later the problem of non-state actors would be revived in the Middle East, but this time there would be no evolution into a new formal state structure.

In 2003 the USA and its allies, most prominently the UK, invaded Iraq in order to depose Saddam Hussein. The legality of the invasion has been repeatedly questioned, and within the nations that supplied the allied forces, there was very vocal opposition from some sectors of the population. Public opinion was increasingly negative as it became all too evident that the attack itself and the plans for post-invasion government were woefully inadequate (Chilcot 2016; Isakhan 2016: 270). Graphic images of the destruction of Iraq's cultural heritage came to symbolize the chaos that the invasion had brought to the country. Television reports (Labott and Clancey 2003) of the looting of the Baghdad Museum, under the noses of American troops, conveyed to an increasingly hostile public that the American military had no interest in protecting Iraqi society and culture (Matthiae 2015: 233–235). Even worse was the subsequent placing of a US base on top of the archaeological site of Babylon (Isakhan 2016: 272–273; Moussa 2008). This decision could not be excused as an oversight in the heat of battle; it pointed to a deeper institutional problem.

It is against this backdrop that some archaeologists began to question the ethical justification for any involvement with the armed forces. Archaeologists and heritage specialists had long been employed by the military as civilian employees in domestic military zones. In the wake of the Iraq invasion, more specialists were engaged in the field to deal with damage, both to the archaeology and to the image of the US military, caused by the conflict. Suspicion of the motives behind these supplementary military-sponsored archaeological initiatives was such that some archaeologists called for a complete boycott, extending even to the conservation of archaeological monuments and artifacts and the drawing up of no-strike lists to protect heritage sites of particular interest (Albarella 2009; Hamilakis 2003).

The debate came to a head at the World Archaeology Congress in 2008 in Dublin (Stone 2011: 4–9). Discussions, which at times became very heated, were polarized between those urging collaboration with the military in order to mitigate the disasters of Iraq and prevent similar events in the future and those who felt that the military were so compromised, both in terms of being there in the first place and subsequently with reference to their behavior, that any contact with them should be shunned. Opinions at the time were strongly held, but within a few years, these debates would fade in importance as events threw up an entirely different conflict scenario.

In 2010 the so-called Arab Spring was the beginning of a series of popular uprisings across six countries of North Africa and the Middle East. As rebel groups fought governments, the spectre arose once again of how to protect cultural heritage when the threat comes from forces outside a state structure. Initially, neither government forces nor rebel groups seemed to be particularly interested in heritage sites, and western governments were wary of direct involvement that would require troops on the ground, though air support was sometimes given. The ground rules were to change significantly when the so-called Islamic State of Iraq and the Syria (ISIS) terrorist group became a threat in 2014. Their political ambitions aimed at a great deal more than overthrowing governments. Their stated desire was to create a caliphate across the Middle East, and they used cultural heritage in practical and symbolic ways to further this aim.

The practical benefit they gained was financial. ISIS forces looted archaeological sites and sold the antiquities to fund their activities. The scale of this has been widely disputed (Tilley 2016). Reliable data for illegal trafficking have always been difficult to come by but, in this case, even more so, as both ISIS and other agencies (see below) had reason to exaggerate the scale of activity. On the other hand, official figures, coming only from verified sources, will almost certainly always be far too low.

Whatever the level of financial support coming from antiquities looting, the symbolic impact of destroying heritage sites and museum collections was probably ultimately of more benefit to ISIS. They filmed their activities and, avoiding mainstream press outlets that would have censored the

material and required verification, released their recordings through social media. Their stated reason was to destroy the work of the infidel, in particular figurative art contrary to the teachings of the Koran (Matthiae 2015: 240). However, there is little doubt that they also intended to sow panic and fear and aimed to promote an image of themselves as invincible warriors through acting out a well-rehearsed role as hero (Harmanşah 2015: 173–176). Isakhan and Zarandona (2018: 11) have stressed how the media images of destruction disseminated by ISIS are carefully planned and executed in order to convey a complex message of religious, historical, and political symbolism. Archaeologists found themselves torn between wanting to pass on social media images in order to raise awareness of the threat to heritage and the realization that this was exactly what ISIS wanted.

Within a few years, the debates concerning the relationship between archaeologists and the military that had dominated Dublin WAC seemed largely redundant. No longer was the danger to heritage in conflict zones coming from negligent national armies, but instead, the threat was dispersed among many and varied unofficial groups that had different agendas. Some of the groups not only endangered heritage through neglect, or using it for military purposes, but actively sought it out to destroy as a propaganda tool. At the same time, there was far less need for archaeologists to fear the impact of regular military forces. For western states, the debacle that became post-invasion Iraq turned the tide decisively against military intervention. Subsequent foreign military personnel operating in the area were usually confined to specialist roles such as humanitarian aid, training, or intelligence work. In June 2015 a new initiative from UNESCO called "Unite4heritage" was launched. Among its activities was the setting up of a task force that drew on the experience of the widely admired Art and Antiquities Unit of the Italian Carabinieri. As well as responding to emergency situations where heritage sites are deliberately targeted, the unit also conducts training on techniques of stability policing so that local enforcement agencies can tackle long-term issues such as looting and trafficking.

Since the period of the Balkans' conflicts, there have also been changes in the way archaeologists are employed in conflict areas, which have raised new ethical considerations. Alongside those employed by state institutions, large museums, and universities, a number of nongovernmental organizations (NGOs) devoted to archaeology and heritage now operate. Some of these are well established, but other organizations have grown up more recently and are usually on a smaller scale. While many do good work and are driven by highly motivated individuals, others are of varying qualities. Privately, some archaeologists have questioned their effectiveness and the risks of funding projects through them, especially in areas that are highly complex geopolitically, where inexperienced workers can constitute a danger to themselves and others. There is a concern that some organizations might be tempted to overstate the threat to heritage in order to gain media attention and maximize their fundraising. This adds yet another element of uncertainty to an already confused situation caused by the absence of reliable data concerning the scale of destruction and the desire of groups such as ISIS to exaggerate the impact of their activities. There have also been concerns that archaeologists focus too much on the heritage in conflict areas without due consideration for the population (Rowlands 2011: 205).

Probably the greatest damage to archaeology in conflict areas in the early twenty-first century has come from widespread looting (Isakhan 2016: 273; Matthiae 2015: 236). Satellite imagery has made all too apparent the scale of the problem across almost all conflict zones, and clearly this has not been limited to groups such as ISIS using antiquities to finance their operations. Ordinary people, their lives destroyed by being caught up in the war, know they can make money by looting their local archaeological sites, and as every archaeologist recognizes, they are very aware of where the sites are located. The people on the bottom rung of this trade get very small sums of money for the objects they steal, usually just about enough to survive on, but as the antiquities pass upward through the supply chain and are traded by middle men, the profits increase dramatically.

Once they cross over the national border and can be traded on the open market, the amounts rise exponentially.

The shady transactions that characterized the art market in the twentieth century have been well documented (Felch and Frammolino 2011). The tough stance taken by the Italian authorities, culminating in the arrest in 2004 of a Getty curator charged with buying stolen antiquities for the museum, sent shock waves through the art world. It was clear that the web of intrigue spread far and wide and included museums, art galleries, conservators, art dealers, academics, and auction houses. The individuals at the top of this murky world were, for the most part, highly educated and privileged, and few seem to have had any moral qualms about their behavior. Indeed many saw themselves as philanthropists working for the good of society, rather than as dealers of stolen property. The Italian police saw things differently. The threat of imprisonment succeeded where decades of negotiation had failed. As a result buying procedures were cleaned up, and many institutions brought in strict rules concerning due diligence, conflict of interest, and provenance checking. However, old habits die hard, and the influx of looted material from the war-torn areas of Syria and Iraq in particular has found an easy path onto the art markets, perhaps not to iconic museums, such as the New York Met or the Getty as in the past, but instead to a plethora of smaller collectors, galleries, museums, auction houses, and dealers. In July 2017 the arts and crafts chain, Hobby Lobby, was fined $3 million and had 5500 antiquities confiscated, because they had been looted from Iraq (Feuer 2017). The objects were widely assumed to have been destined for the Museum of the Bible, under construction in Washington, DC, and owned by Hobby Lobby's President, Steve Green.

Undoubtedly the continued success of illegal antiquities looting is related to the relative ease of the operation, the improbability of detection, and the light sanctions imposed even if caught. However, antiquities would not be looted if there were not a market for them, and this is an area where many within the field feel that archaeologists could be more ethically aware. If museums and art galleries did not buy items without full documentation, if auction houses investigated provenance more diligently, if academic publishers refused to publish works that contained information on looted objects (which has been demonstrated to raise the value of an item on the illegal market), if scholars refused to verify the authenticity of looted objects, if archaeologists thoroughly recorded and published all their excavations, and if museums had a complete database of their collections with full descriptions and photographs, these measures, taken together, would substantially impact the illegal art market. Ultimately, it is the ethical decisions made in the small, unheroic, daily acts of archaeologists' professional lives that have the greatest impact.

In one sense the ethical priorities today are little different to those of previous generations of archaeologists, but, whereas our predecessors were often unaware of larger geopolitical forces and ill equipped to see how their work might fit into a broader agenda, current dilemmas stem from the opposite problem. We have to make sense of a surfeit of information of varying reliability, we hear a multiplicity of voices and viewpoints, and we live in a world of instantaneous global communication capable of provoking a concatenation of events with unintended consequences. The 1954 Hague Convention seems to hark back to an era where sides to a conflict could be relatively easily defined. Today's fast-moving, complex, interconnected world presents us with a more fragmented scenario that we often struggle to comprehend and that requires a constant reassessment of ethical choices.

Arnold, Bettina

Bettina Arnold
Department of Anthropology, University of Wisconsin-Milwaukee, Milwaukee, WI, USA

Basic Biographical Information

Bettina Arnold obtained her B.A. in Archaeology from Yale University in 1983 and her M.A. and Ph.D. degrees in Anthropology from Harvard University in 1986 and 1991, respectively. She is professor of anthropology at the University of Wisconsin-Milwaukee, where she was the codirector of the Center for Celtic

Studies from 2000 to 2009 as well as the coordinator of the Museum Studies Graduate Program from 1996 to 2012. Her area of expertise is the Pre-Roman European Iron Age, but in the course of her career, she has participated in archaeological projects ranging from the Middle Bronze Age through the early medieval period in Western Europe.

Major Accomplishments

Since 1999 she has codirected an excavation project in southwest Germany focused on the burial record of the early Iron Age Heuneburg hillfort and its environs; two burial mounds associated with this site were excavated by the Landscape of Ancestors project between 1999 and 2002. Finds from those excavations were featured in *Die Welt der Kelten: Zentren der Macht – Kostbarkeiten der Kunst*, a major exhibition in Stuttgart in 2012–2013. Her work has been directed toward the following specific research topics: the archaeological interpretation and analysis of complex societies, particularly as reflected in mortuary contexts; material culture as a symbolic system and a means of communicating social relationships; the archaeological interpretation of prehistoric gender configurations in burial contexts; and the sociopolitical history of archaeology and museum collecting, especially their involvement in identity construction in the nineteenth- and twentieth-century nationalist and ethnic movements in Europe and the United States. She published a groundbreaking article on the use and abuse of archaeology for political purposes in Nazi Germany in *Antiquity* in 1990 that has been reprinted repeatedly since its first appearance. In addition to founding and acting as editor of the online peer-reviewed journal *e-Keltoi*, she is a member of numerous editorial boards, including the *History of Archaeology* series for Oxford University Press and the *History of Archaeology Commission* of the UISPP.

Dean E. Arnold. (Photo courtesy of Dean E. Arnold and Wheaton College Marketing Communications)

Basic Bibliographic Information

Dean Edward Arnold is an acclaimed scholar internationally known as one of the founders of ceramic ethnoarchaeology, specifically the organization and technology of pottery production, which is a subject of his classic book *Ceramic Theory and Cultural Process* (Arnold 1985, 2011). (Carol Kramer and William A. Longacre were later progenitors of this field of scholarship.) His long-term comprehensive analysis of a single pottery-making community in Yucatán, Mexico, is, to our knowledge, the longest, continuous academic study of any craft production – pottery or other material culture anywhere – documenting synchronic and diachronic changes over nearly five decades. Arnold is a keen observer and prolific scholar, lecturer, and writer, sharing his knowledge with his peers in the Americas and Europe. He continues to contribute to the profession and is currently writing another book, to date having authored five books, co-edited two books, and written more than 70 articles and book chapters about potters, pottery production, and related subjects covering topics ranging from the ecology of production to the standardization of ceramic pastes and the social organization of potters. Currently, Arnold is an adjunct curator, Social Sciences Section (Anthropology) in the Integrative Research Center, at The Field Museum in Chicago, where he continues his research in Latin American anthropology. He is also professor of anthropology (emeritus), Wheaton College, Illinois, since July 2012, having served on its faculty for 39 years.

Arnold received his B.A. in anthropology from Wheaton College, Illinois, in 1964 and an M.A. in anthropology at the University of Illinois Urbana-Champaign having submitted a thesis entitled *Maya Blue: A New Perspective* (1967a) – published as *Sak lu'um in Maya culture and its possible relationship to Maya Blue* (1967b). His thesis advisor, Donald W. Lathrap (1927–1990), an American archaeologist, had studied under Alfred L. Kroeber and Carl Sauer at the University of California, Berkeley, and had taken his doctorate under Gordon R. Willey at Harvard University in 1962. Lathrap specialized in the study of Peru and Amazonia and would again serve as Arnold's doctoral advisor. Following fieldwork in Peru, Arnold received his Ph.D. in anthropology at Illinois having written *The emics of pottery design from Quinua, Peru* (1970) as his dissertation, later publishing several articles derived from his dissertation fieldwork in the Peruvian highlands (1972, 1975, 1983, 1993, 1998, 2005a). The influences of Kroeber, Willey, and Lathrap may be seen in Arnold's research. During his undergraduate studies and his matriculation at Illinois, he was exposed to all four fields of anthropology (archaeology, ethnology/anthropology, human biology, and linguistics) and during his subsequent academic and research career would make use of all of them in teaching and research (e.g., Arnold 2005a, 2005c; Arnold and Frisbey 1972, Neuenswander and Arnold, eds. 1977). Arnold was awarded a National Defense Foreign Language fellowship (1966–1969) and in 1969 received the Fourth Prize in the Sigma Xi Student

Paper Competition at the University of Illinois Urbana-Champaign.

He spent 3 years teaching at the Pennsylvania State University as assistant professor of anthropology (1970–1973) and conducted research in the Valley of Guatemala as a member of the Kaminaljuyú Project directed by William T. Sanders, where he studied pottery making in the Valley, later using these data as pioneering work in what some have called ethnoarchaeometry (Arnold 1978; Arnold et al. 1978, 1991, 2000; Neff et al. 1990). Arnold next went to the Universidad Nacional San Antonio Abad in Cuzco, Peru, as a Fulbright lecturer and also worked with the National Institute of Culture excavating an Inca storage/habitation site called Cata-casa-llaqta above Cuzco. He returned to Wheaton College in 1973 as a faculty member in the Department of Sociology and Anthropology, beginning as an assistant professor of anthropology (1973–1977), and was promoted to associate professor (1977–1982) and then to full professor (1982–2012). Arnold was a Fulbright scholar a second time in México in 1984 with an American Republics Research Grant, enabling his return to Yucatán, México, to continue his study of potters in the city of Ticul that he began in 1965. He has also done archaeological fieldwork in the American Southwest and archaeological research in the tropical forests of Bolivia (Arnold and Prettol 1988), but his primary, ongoing research interest was the long-term study of the relationship of social and technological change among potters in Ticul, Yucatán, México, having studied them extensively over a period spanning 43 years. As noted, this work is remarkably the longest, continuous academic study of any craft production – pottery or other material culture. At Wheaton – a Christian, residential, and highly ranked liberal arts college and graduate school, Arnold taught 22 different courses, most frequently: Introduction to Anthropology, Biculturalism, Human Origins, Medical Anthropology, Ceramics and Culture, Cross-Cultural Ethics, Latin American Peoples, and Pre-Columbian Civilizations, as well as the Senior Capstone class.

Arnold was also a research associate at the Field Museum of Natural History in Chicago, now The Field Museum (1988–1990, 1993–2011). In 1996, having been nominated by his peers, he was awarded the Society for American Archaeology's Award for Excellence in Ceramic Studies. He was also honored as a Fellow of the American Anthropological Association and Fellow of the American Association for the Advancement of Science (AAAS). Arnold was Visiting Fellow at Clare Hall, a college of the University of Cambridge (1985), is a lifetime member of the college, and was a three-time visiting scholar in the Department of Archaeology in the University (1985, 1992, and 2000). Additionally, he participated in numerous academic conferences including the annual meetings of the Society for American Archaeology and the American Anthropological Association. The latter is also the venue for annual Ceramic Ecology Symposia where he often presented his current research and previewed his forthcoming articles and book chapters (Mouat and Arnold 1988).

In 2003 Arnold was awarded the Charles R. Jenkins Certificate of Distinguished Achievement by the National Executive Council of Lambda Alpha and in 2008 was recipient of the Distinguished Service to Alma Mater Award from the Wheaton College Alumni Association (Wheaton College 2008a, 2008b). His ability to relate anthropological topics and Christianity is remarkable (Arnold 2005b, 2006b; Moshier et al. 2007). He was a High Table Member of Corpus Christi College at the University of Cambridge in 2000 and was recognized as a Distinguished Member of the American Anthropological Association in 2017. In addition, he was previously selected for inclusion in the 1st edition of *Who's who of emerging leaders in America* (1987) as well as multiple editions of *Who's who in the Midwest* and recently received the Albert Nelson Marquis Lifetime Achievement Award. He and his wife, June, the recently retired Director of Health Professions at Wheaton, have two grown daughters, Michelle and Andrea, and four grandchildren.

Major Accomplishments

Arnold, in a recent AAAS interview, stated that although he was very interested in and had written a great deal about pots and potsherds, "It was the potters that fascinated me. Archaeologists are not

very well informed about how people made pots, and about how potters lived. That's the thing that drives me" (O'Hara 2012). This cogently sums up the philosophy behind his extensive ethnographic research on pottery production, using the study of contemporary potters to evaluate assumptions archaeologists use in their study of the past. Arnold's accomplishments and contributions to ethnography, archaeology, and ceramic studies may be viewed in several formats (by chronological phases, geographic regions, and/or topics); these are combined below. His physicochemical studies of Peruvian and Yucatecan pottery and ceramic materials (Arnold 1971, 1972), with geologist Bruce Bohor (1975, 1977) and archaeometrician Hector Neff (Neff et al. 1988, 1990) and with a host of others (Arnold et al. 1991, 1999, 2000, 2007a, 2008, 2012) illustrate his research skills. Arnold's contributions to ceramic ecology (1975, 1991; Mouat and Arnold 1988) and to our understanding of the intricacies of pottery production – including forming techniques (1999; Arnold et al. 2007b), standardization (2000; Arnold and Nieves 1992), potters' organization (2006a, 2008, Arnold et al. 2013), production analysis (2017a), culture change (2008, 2012, 2015, 2017b), and even conducting fieldwork (1995) – are without equal in the archaeological and anthropological literature.

Arnold's most salient accomplishment lies in the esteemed book he wrote early in his career, *Ceramic Theory and Cultural Process*, published by Cambridge University Press (1985) which has stood the test of time. The author's status in ethnoarchaeological studies was evident in being asked to examine critically his own research and reflect upon it a quarter century after its publication (Arnold 2011). He drew upon the theoretical perspectives of systems theory, cybernetics, and cultural ecology and utilized cross-cultural comparisons to help elucidate the origins and evolution of the pottery-making craft. In the 1980s this was an innovative approach to the archaeological interpretation of ceramics, since the book was about ceramic production and not about the pottery itself; it concerns the relationships between ceramics, the potters themselves, the environment, and culture and society. It challenged the traditional belief in anthropology that because clay is plastic, culture was the only variable that affected ceramic production. His book focuses on generalizations, not universals. His second book, *Ecology of Ceramic Production in an Andean Community*, also published by Cambridge (1993), was written originally as a sequel, linked the ecological (physical and biological environments), historical, and archaeological contexts of pottery production in Quinua, Peru, with broader implications for those individuals concerned with archaeological ceramics of the Andean Middle Horizon. This volume expanded his prior *Current Anthropology* publication (1975), challenging beliefs held by Alfred L. Kroeber, John Rowe, and others.

Three subsequent books on ceramic ethnoarchaeology are a trilogy that is a synthesis of four his decades of research on the pottery-making community in the city of Ticul. In *Social Change and the Evolution of Ceramic Production and Distribution in a Maya Community* (2008), Arnold focuses on the important questions of how and why ceramics and their production changed through time between 1965 and 1997. Potters had become aware of new changes in forming and firing methods and were acculturated; at the same time, consumer demand fluctuated, and political and economic systems changed. In this new climate, Arnold reports and evaluates these by tracing social change among potters and transformations in the production and distribution of their pottery in this Mexican community. A second volume, *The Evolution of Ceramic Production Organization in a Maya Community* (2015), was a follow-up that examines how social and spatial organization of units of pottery production change diachronically. The focus is on production personnel and the spatial organization of their workplace in Ticul including traditional household and the development of new types of production organization. Massive social change and the reorientation of pottery production to the tourist market are documented. Recently developed entrepreneurial, attached, and government-sponsored workshops were short-lived but did not persist. The changing production organization also reveals that intermittent crafting, multi-crafting, and risk management also play important roles disclosing the complexity of the craft production in the present and in antiquity. He also provides valuable illustrations and floor plans of
